PREFACE

A big project like this *Handbook* means that you incur debts, and not only to your authors and your publisher. As editors we, along with our colleague Elaine Unterhalter who edited the section on postcolonialism, would like to thank most warmly those authors who delivered on time, and who did not fuss but just got on and did a first-rate job. We would also like to thank all authors who did deliver – which was almost everyone we asked. We know that some of our authors worked in very difficult private circumstances as they were finishing their chapters and we hope the publication of the Volumes will, later, be for them a happy reminder of difficulties and disasters overcome.

The only sad theme is that some very close colleagues, with whom we were working and for whom we had the greatest respect and liking, became very ill (and died) while the volumes were being prepared. We decided to ask for copyright permissions to publish something of theirs. These permissions were graciously given by two major journals and with the agreement also of our publishers Springer, Rolland Paulston and Terry McLaughlin have examples of their writing in this *Handbook*.

We know it is going to embarrass her and she no doubt will take advantage of working in the same building to reprove Bob Cowen directly, but we wanted especially to note the major contribution to these Volumes of Elaine Unterhalter who combines a genuine independence of mind and spirit with a charming sense of what it is to work in a small team, to soak up pressure and to deliver on time. We are very grateful to her and to her colleague Helen Paulsen who provided us with technically perfect copy, address lists, Notes on Authors, Abstracts, and so on. We had problems enough of our own – it was a treat to deal with another small team that did the job faster, more neatly, and with less fuss.

Our two institutions – the Institute of Education within the University of London and the University of Wisconsin-Madison – provided crucial infrastructures for controlling the project, notably computing services backed by the inestimable assistance of Apple specialist Jem Dowse in the Institute and the last-minute computer skills of Lefteris Klerides which helped keep Bob Cowen calmer than he thought he was going to be.

However, it was not just an infrastructure thing. Both of us were in each other's universities from time to time and Bob Cowen would like to thank Tom Popkewitz and Mike Apple who made him feel especially welcome in Wisconsin and Andreas

Kazamias would like to thank Jagdish Gundara and Gerald Grace who made him feel especially welcome inside the Institute of Education. Much of the project was actually edited in a small office inside Bob Cowen's new 'department' – Curriculum, Pedagogy, and Assessment – in the Institute of Education which was reorganized internally during the life of this project. He would like to thank colleagues within Curriculum, Pedagogy, and Assessment for welcoming a relative stranger – especially Denis Lawton with whom Bob (and Andreas for much of this project) was privileged to share a room. With the calm wisdom for which Denis is famed, he planned his visits to the Institute with exquisite care for quite some time.

We thank him and all other colleagues in many countries – it is the unexpected extra kindnesses which is so touching – for their help and support. The project finally got completed. We are still not exactly sure how; but it did. Like many other people we also look forward to reading the Volumes. It is difficult to grasp their full scope and complexity. They contain some surprises and a flurry of implications – captured in the writing of our authors – for future work in comparative education.

Robert Cowen and Andreas Kazamias

JOINT EDITORIAL INTRODUCTION

Robert Cowen and Andreas Kazamias

We are doing well...? In some ways, yes. The field of comparative education began to grow again around the millennium.

Texts from the late 1990s and early years of this, the new, century include: Robin Alexander, Patricia Broadfoot & David Phillips (Eds.) *Learning from comparing: New directions in comparative education research* (Symposium Books: Oxford) 1999; Robert Arnove & Carlos Alberto Torres, *Comparative education: The dialectic of the global and the local* (Roman & Littlefield: Lanham, Maryland) 1999; Edward R. Beauchamp (Ed.) *Comparative education reader* (Routledge/Falmer: New York/London) 2003; Mark Bray (Ed.) *Comparative education* (Kluwer: Dordrecht/Boston/London) 2003; Nicholas C. Burbules and Carlos A. Torres (eds) *Globalization and education: Critical perspectives* (Routledge: New York/London) 2000; Michael Crossley's and Keith Watson's *Comparative and international research in education: Globalisation, context and difference* (Routledge-Falmer: London/New York) 2003; Andreas Kazamias and M. Spillane (Eds.) *Education and the structuring of the European space: North-south, centre-periphery, identity-otherness* (Seirios Editions: Athens) 1998; Antonio Nóvoa and Martin Lawn (Eds.) *Fabricating Europe: The formation of an education space* (Kluwer: Dordrecht/London) 2002; Sonia Mehta and Peter Ninnes (Eds.) *Re-imagining comparative education* (Routledge/Falmer: New York) 2004; Jurgén Schriewer (Ed.) *Discourse formation in comparative education* (Peter Lang: Frankfurt-am-Main) 2000; Nelly P. Stromquist and Karen Monkman (Eds.) *Globalization and education: Integration and contestation across cultures* (Rowman & Littlefield: Lanham/Boulder/New York/Oxford) 2000 – and all this is without mentioning the flurry of new books in the last year or so – a new book on comparative education research (edited by Bray, Adamson, and Mason); a collection of articles from the journal *Comparative Education* (edited by Crossley, Broadfoot, and Schweisfurth), a study of the professional Societies of Comparative Education; and recent books by Phillips and Schweisfurth, Donatella Palomba, and Sprogøe and Winther-Jensen.

The journals are also numerous. They include *Comparative Education* (the UK), *Comparative Education Review* (USA), *International Review of Education* (UNESCO/Hamburg), *Canadian & International Education* (Canada), *Compare* (the UK), and *Prospects* (UNESCO). There are also other journals (e.g. in French and in Spanish) which frequently carry comparative articles or which like *Propuesta Educativa* (Argentina) offer occasional special issues devoted to comparative education, or are

entirely comparative in content, like the Greek *Synkritiki kai Diethnis Ekpaideutiki Epitheorisi* (Athens).

The advanced study of comparative education is widely institutionalised, in graduate schools. For example, in the English-speaking world in the United States, Columbia University, Florida State University, Harvard University, Ohio State University, University of Pittsburgh, University of Maryland, State University of New York at Buffalo and at Albany, University of Illinois, University of Wisconsin, University of California at Los Angeles, University of Southern California, Stanford University, Loyola University, and University of Hawaii are some of the major centres. Australia, Canada, England, New Zealand, and many of the anglophone African countries – notably South Africa – also have graduate school programmes. In continental Europe, there are specialised courses in comparative education in Belgium, Denmark, Finland, France, Germany, Greece, Italy, Malta, Norway, Portugal, Spain, Sweden, and the Netherlands. Overall, the institutionalisation of comparative education is increasing not merely in Southern and Eastern Europe but also in the older metropolitan university centres, as universities internationalise their programmes and absorb a market of ‘overseas’ students.

Similarly in terms of its international networks and its conferences, comparative education is doing exceptionally well.

But how is it doing intellectually? That is, what kind of concerns and what kind of academic work is being, and has been, done in ‘the field of study’ called comparative education – primarily from a university base? Where are we? And where are we going?

The two volumes of this handbook make an effort to outline the situation. As editors we have used a number of principles.

In the way we have arranged the volumes there are a number of general arguments. These may be summarised as follows:

1. Both volumes argue that what is judged to be ‘good’ comparative education has changed over time. They analyse the shifting academic agendas, the changing perspectives of attention, and the different academic languages used to construct ‘comparative education’. They ask why this happens – why does ‘comparative education’ change its epistemic concerns, its reading of the world, and its aspirations to act upon it? They show the ways in which comparative education responds to the changing politics and economics of real events in the world as well as to the intellectual currents that are strong in particular times and places. The consequence is that several comparative educations can be identified, both at any one particular time and over time, and that comparative education is continuing to change with the new readings of the world which are emerging now.
2. There are some things which the handbook is not, and is not intended to be. It is not an encyclopaedia covering the comparative education world (and scholars within it) alphabetically. It does not offer ‘national case studies of education’ – that stuff was out of date 50 years ago. In particular, the Volumes do not assume that the nation state is the correct unit of analysis in comparative education. Nor does

the handbook embark on a series of case studies of the condition of 'comparative education' in Argentina, Brazil, Canada, Denmark, etc., and bewail the fact that comparative education is relatively weak in 'the south' or 'the east' and insist that the job of the handbook is to correct that imbalance. Constructing a comparative education in 'the south', for the south, and of the south is a mite more complex than that, even when the political cliché of The South has been deciphered.

3. Thus the handbook is an account of how a field of study was, is, and is becoming within the politics of its times. It analyses the construction of comparative education in the nineteenth and twentieth centuries particularly in Volume One. Volume Two shows how lively the contemporary field is, within the new politics of our times.
4. The handbook is a major statement of the condition of a field; it is not a fashion statement. Thus the future of comparative education is addressed in the handbook, especially in Volume Two, but it is not addressed with the rash confidence of conviction that the future is about the clash of civilisations; or the future is more globalisation; or that all that is needed is a better understanding of one (identified and specific) intellectual perspective.
5. The handbook is written at a turning point in the history of the field, and thus it leaves the future of the field open while offering a wide range of ways to talk about that future.

The handbook is divided into two volumes with four sections each.

In Volume One, Section 1 shows the construction of comparative education as a discourse, including the construction of comparative education as a university discourse, up to the late 1970s. The section also notes that 'comparative education' in its nineteenth- and twentieth-century framing was an ideological project for action on the world – practical policy makers were in the nineteenth century using a comparative perspective to construct a new social technology: mass elementary education and national systems of education. Thus the broadest theme of this section of the handbook is how the field of study sees its past in political context. The narrow way to understand the section is to see it as the identification and analysis of specific epistemological paradigms which, over time, framed comparative education in social context.

Section 2 deals with the world and the world of comparative education after the 1980s: the rethinking of the classical assumptions and approaches whose construction was described and analysed in Section 1.

Section 3 is partly devoted to the theme of 'comparative action', that is, those actions upon the world and upon the educational world which are based upon a comparative assessment of it. The strategic themes which the authors were invited to address as they undertook their descriptions and analyses were: (a) what was the political agenda for the activities; (b) what was the view of the international state system which framed the political action and the educational reform; (c) what was the view of the relationship between culture, economies, and education; and (d) what concept of comparative education was made visible?

Section 4 is concerned with the shift from anxiety about the relationships between educational systems and industrial economies in the nineteenth and twentieth centuries

to the relationships of educational systems and emerging knowledge economies in the late twentieth and early twenty-first centuries. This section thus deals with some of the classic patterns of reforming educational systems to make them more ‘relevant’ to industrialisation and to the disputes and resistances – and very different patterns of education – which were a consequence. However, the concerns are not merely historical. The same ‘economic imperative’, which caused so much anxiety in the nineteenth and twentieth century, is taking a contemporary reprieve under the rubric of ‘globalisation’ and ‘knowledge economies’, occasionally informed by views of neo-liberalism. What is the nature of that contemporary debate?

In Volume Two, the emphasis is on how the world changed – and how this affected ways of thinking in a range of comparative educations. Thus Volume Two of the handbook exemplifies some of the important new concerns and visions of comparative education: rapid transitions in societies; the new emphasis on teaching and learning; the search for the recovery, reinvention, and creation of identity and of future identities, including ideas of ‘postcolonialism’; and – again – the current sense of what constitutes ‘globalisation’.

Therefore Volume Two very carefully avoids a conventional treatment of schooling systems and descriptions of educational reform in many ‘nation states’; or the description of educational systems sector by sector – elementary, secondary, teacher education, and so on; and it avoids the ‘comparative’ descriptions of educational trends and processes on a country-by-country basis or regional basis.

Within that general framing, Section 5 in Volume Two of the handbook deals with postcolonialism. This is a growing area in comparative education, at the intersection of political science, literary studies, linguistic theory, and history. The concerns which are central are those of identity and language, the formation and reformation of post-colonial politics and polities, the postcolonial terms of discursive contestation, shifts in the nature of the State, and new theories of rights. This is not only an extremely interesting area for comparative exploration, it is also a difficult area of new theorising and we asked Elaine Unterhalter – whose South African experience and interests in gender, rights-theory, capability-theory, and ‘development’ come together around the theme of postcoloniality – to edit this section of the two volumes.

Section 6 deals with comparative studies of ‘the educated person’ as constructed through schooling, and pedagogical cultures at different times and in different places. Thus this section explores the revision of knowledge traditions and the construction – the making and taking – of pedagogic identity, a theme which has a long history in comparative education, but which through the work of academics such as Basil Bernstein and Tom Popkewitz, feminists and advocates of positional identities (such as American blacks), and some curriculum specialists is being revitalised. As the nature of educational sites alters in late modernity, the issue of educational cultures and pedagogic identity becomes powerfully de-linked from notions of citizenship and more and more powerfully linked to economics or to religion. The framing of the topics of culture, knowledge, and pedagogies is thus changing rapidly and a comparative education of the future must work out new ways to analyse the theme of identity.

Sections 7 and 8 ask about ways forward. They ask, after Sections 1–6: is there anything else to talk about? The answer is, yes. The volumes finish with a range of fresh proposals for new kinds of comparative education.

ON HISTORY AND ON THE CREATION OF COMPARATIVE EDUCATION

Robert Cowen

Max Eckstein and Harold Noah do not know this but I have for years liked both of them very much. At the personal level, I was most touched when they were the first in the comparative education community to warmly welcome me to the USA where, rather to my surprise, I found myself teaching sociology and comparative education in a good university at graduate school level. Professionally, they had also, earlier, solved one of my problems as a student: where is there a history of comparative education? It was there in their classic text (Noah & Eckstein, 1969). Here the origins of the field were set out with exemplary clarity. The footnoting was scholarly and clearly a flurry of research had been done. As someone who was thinking about specialising in comparative education I was most relieved that there was a history – and there was also that marvellous account in Bereday's book (1964) about scholars in other countries and their universities and departments. Comparative education existed and it had a history as well. There were more jobs in sociology, but clearly comparative education was more fun. I could take up a career. The history legitimated me.

And now – a few decades later? Now that we are all legitimate, in what senses do we exist historically?

The first difficulty is we have a lot of unseen history and not enough labour to make it visible. We have archives in major universities, but not enough obvious reward for young scholars to undertake research on them. We have marvellous bits of private writing on the history of the field – Peter Hackett and Richard Rapacz come to mind – but we have no one who has brought these correspondences (in both senses) together. At least a start has made by Gita Steiner-Khamsi and others on oral history (clearly something which the Comparative Education Society in Europe ought to undertake also as rapidly as possible). But – again – the initial problem is the career difficulty of being labelled as a specialist in the history of comparative education.

The second difficulty is the massive amount of effort required to get one of these serious historical projects going – a point made with great clarity in the Acknowledgements at the beginning of the book *Common Interests, Uncommon Goals* (Masemann *et al.*, 2007). There are very practical problems in writing histories – in the ways that these must be done if you work seriously on researching history. Miguel Pereyra for example has been working hard and long on analysing Kandel as a scholar in the history of comparative education – but to chase down material on Kandel has meant major travel and expense which can just about be

handled by a scholar in mid-career with major effort – but there are few structural supports for such historical scholarship.

The third difficulty is that, given the invisibility of a large amount of information, we simply do not have the density of information which makes for good history. The amount of material that goes into a first rate historical account of something is astonishing. Dalrymple's work on *The Last Mughal* (2007) – so brilliantly contextualised – is dependent upon a complete new bit of the national archive becoming visible. Herman's work on *The Scottish Enlightenment* (2006) is dependent upon a massive bibliography of earlier specialist and detailed texts. Major histories – whether these are by Norman Davies (1997) or by Tony Judt (2007) – draw on bibliographies which take a chapter-length essay merely to list. An obvious counter-argument may be offered – such work is 'mainstream' history (though that is an odd expression given what historians now study) – and, the counter-argument might continue, the comparison is unfair: all we are talking about here are histories of fields of study. But that last proposition, in turn, is not convincing in the face of texts such as Randall Collins' book on *The Sociology of Philosophies* (1998), Friedrichs' book (1970) on sociology or even a monograph on a field of study such as Bartholomew (1989) on the formation of science in Japan.

Right now, we simply do not have enough material to move on from the huge amount of work which is already involved in putting together the essays in this section of the handbook. The scholarly apparatus of all of the chapters in the section is impressive and the scholarly apparatus of some of the chapters is amazing. But we are still short of material.

The problem is also worse than that because a history of comparative education ought – sooner or later – to become a comparative history of comparative education.

We are still a little bit away from that – although it is worth remembering that the 'history' of comparative education in these volumes is not limited to this first section. Reading the chapters in the other sections of the volumes – Larsen on history, Steiner-Khamsi and her conceptualisation of the development of comparative education, the exploration of comparative education in East Asia outlined by Wang and Dong and Shibata, the concept of voices which Mehta raises, the mappings of Paulston, the analysis of Popkewitz – reminds us of possibilities and thematics in a potential comparative history of comparative education.

There is also the shiver of the shock which comes later, as a reading of these volumes is complete, and it is recalled that we have no serious history of comparative education in Brazil or in Argentina in print – and this despite the significance of Sarmiento in Argentina and his political views and his astonishing practical 'comparative education' or the significance of Anísio Teixeira and his international connections in Brazilian educational history. (Of course articles in our specialist journals exist on both people with good hints about where a 'history' might go, but that is just my point. We have articles and hints; and we do not have histories.)

We have not even brought together seriously the 'individual' histories of comparative education in France, Germany, Italy and so on – though again in at least three book chapters or articles by Wolfgang Mitter (one appearing in Volume 1) you can find ways into a fuller comparative history.

So, let us be optimistic like a cheerful and happy child. Let us assume that a major foundation such as the Gulbenkian or Hoover decides that a comparative history of comparative education would be well worth funding. Apart from establishing an Advisory Board with such senior scholars on it as Eckstein, Noah, Kazamias, Mitter and Rust, what would we wish our team of actual researchers to make visible as evidence for this putative history so that our material for writing that history became denser and denser?

Almost certainly it would be necessary to review the history of other fields of study including comparative study (Schriewer, 2006). It would be necessary to make women visible – they are there in history but they (e.g., Ann Dryland, Madame Hattinguais) are not there in our histories. I suspect it will also be necessary to make fuller sense of the meta-epistemic assumptions of a range of comparative educations in a range of countries: for example the effect of structural-functionalist sociology in the USA on American comparative education but the relative lack of effect by the Frankfurt School; the fear of sociology which so characterises the ‘culturalist’ school – though not Lauwerys – in the Institute of Education and Kings College in London in the late 1950s and early 1960s; the sudden lurch in vocabulary which inserts ‘international’ as a qualifier of, or as a juxtaposition to, ‘comparative’; and the reasons for ‘a linguistic turn’ or a ‘post-modern turn’ or even the new vocabulary that implies a ‘geographic’ turn in a number of social sciences, including a hint of it within comparative education.

Also – amazingly – we do not have a really sharp, historian’s sort of account of the life of George Bereday, or Joseph Lauwerys and his work for UNESCO, his links with Piaget, the IBE, with Teixeira and with Hiratsuka in Japan. Both Bereday and Lauwerys linked persons and ideas across cultures and continents and for quite justifiable reasons – including their impact on their own institutions, and on the societies of comparative education and on generations of graduate students as well as their astonishing lecturing skills – Bereday and Lauwerys are well known in the field of study; but they indirectly raise a broader question.

We do not understand our own iconographies. For example, Sir Michael Sadler was clearly a fine public servant and an educational leader and, one suspects, a rather pleasant human being. Fine – but we give him an astounding importance in comparative education even though that famous essay of his (Sadler, 1964) has caused far more confusion than it has ever solved. But he is always in ‘the histories’, which itself becomes a historical problem of the social construction of our iconographies. No doubt a comparative history of comparative education would explore whether such iconographies also have been inserted into the invention of the tradition of comparative education in Japan or Germany or France.

The final paradox of course is that while ‘the evidence’ can be made available, pre-prepared as it were by stabilising and strengthening archives and by making hidden ‘facts’ more visible, the questions cannot.

Somewhere in this first section on the creation and recreation of the field of study, Andreas Kazamias – who is and always has been deeply committed as a historian to doing an immense amount of work on the history of the field of study – has a quotation

from T.S. Eliot. The quotation confirms in a subtle and elegant way one of Andreas' own convictions – that each generation must rewrite its history.

That almost leaves us with a paradox. The propositions of Eliot and Kazamias create the thought that it is the future which determines the past. Yes, I know neither of them said that. But the possibilities are exciting. The quotation from Eliot reverberates. Our contemporary histories of ourselves need revisiting now and will need revisiting again frequently in the future.

THE MODERNIST BEGINNINGS OF COMPARATIVE EDUCATION: THE PROTO-SCIENTIFIC AND THE REFORMIST-MELIORIST ADMINISTRATIVE MOTIF

Pella Kaloyannaki and Andreas M. Kazamias

Introduction

The modernist beginnings of comparative education (CE) as a field of study are conventionally traced to the post-Enlightenment period in the early and mid decades of the nineteenth century, specifically to the pioneering work of Marc-Antoine Jullien de Paris and to discourses of educational policy-makers, reformers and administrators in Europe and the United States, such as Horace Mann, Calvin Stowe and Henry Barnard in the United States, Victor Cousin in France and the poet-school inspector Matthew Arnold in England. First, this chapter analyses in some detail Jullien's ideas about CE—its methodology, epistemology and ideology—as reflected mainly in his now famous *Esquisse et vues préliminaires sur un ouvrage sur l'éducation comparée* (*Plan and Preliminary Views for a Work on Comparative Education*), published in 1817, on the basis of which Jullien has been acclaimed as 'the father' of CE. Here Jullien's conception of CE will be referred to as representing 'the proto-scientific humanistic and meliorist motif' in the history of the field. Second, the study examines in lesser detail what may be called 'the reformist-meliorist motif in comparative education', which refers to discourses about foreign education as reflected in the relevant texts of nineteenth-century policy-makers, reformers and administrators like Victor Cousin of France, and Horace Mann, Calvin Stowe and Henry Barnard of the United States.

The Proto-Scientific Humanistic and Meliorist Motif: Marc-Antoine Jullien de Paris

The Man, His Work and His Times

Marc-Antoine Jullien de Paris was born in Paris in 1775, from highly educated parents in the humanities (philosophy, language, literature and the classics). At a young age and for a short period he served as a journalist for the Jacobins and the French National Convention, and was a diplomat and legionnaire in the service of Napoleon Bonaparte. He travelled widely in Europe, visited England and Scotland and also went to Egypt as a war commissioner in Bonaparte's expedition there. Throughout most of his life

until his death in 1848 he devoted his time to the study of education and pedagogy on which he wrote books, monographs, essays, reports and memoranda. During the years 1819–1830, Jullien founded and directed the journal *Revue encyclopédique ou Analyse raisonnée de productions les plus remarquables dans la littérature, les sciences et les arts* (*Encyclopedic Review or Reasoned Analysis of the Most Remarkable Productions in Literature, Sciences and the Arts*) for which he wrote, among other things, on public education in Switzerland, Belgium and Spain.

Jullien's interest in education began quite early in his life, during the period of the French Revolution, and continued thereafter until his death. According to his biographer R. R. Palmer, Jullien started writing books on the subject in 1805 while he was serving in the French army. As a theorist of education he was especially attracted to the pedagogical ideas of the famous Swiss educators J. H. Pestalozzi and P. E. Fellenberg whose schools he had visited at Yverdon and Hofwyl, respectively, in Switzerland (Palmer, 1993). According to Fraser, in his authoritative edition and translation of Jullien's *Plan*:

Until his death ... Jullien was engaged constantly in scientific and cultural affairs. He founded the Société Française de l'union des nations, and invited international scholars to his home for monthly dinners. He traveled continually, attending international congresses, devoting his time to learned societies, and corresponding with statesmen and educators whose cosmopolitanism sought to evade the confines of nationalism as it consolidated itself in Europe (Fraser, 1964:12).

In Jullien's life and works, one can distinguish certain elements which, in combination with each other, had an effect on Jullien's pioneering ideas in the promotion of the *episteme* ('science') of comparative education. Jullien was also nurtured in the ideas and spirit of the Enlightenment 'paradigm of modernity' with its emphasis on reason/rationalism, empiricism, science (including social science), universalism, secularism, progress and the nation state. Not unsurprisingly, he became interested in the scientific study of education.

Comparative Education as 'Almost Nearly a Positive Science'

Jullien envisaged 'education' and a fortiori comparative education, to be a 'nearly *positive science*' (*science positive*) analogous to comparative anatomy. In the *Plan* he explained:

Education, as all other sciences and all the arts, is composed of facts and observations. It, therefore, seems necessary to form, for this science as one has done for other branches of knowledge, collections of facts and observations, arranged in analytical charts, which permit them to be related and compared, to deduct from them certain principles, determined rules, so that education might become almost nearly a positive science. ... Researches on *comparative anatomy* have advanced the science of anatomy. In the same way the researches on *comparative education* must furnish new means of perfecting the science of education (Fraser, 1964:40–41).

To make comparative education a ‘nearly positive science’ Jullien developed the aforementioned *Plan (Esquisse)*. The *Plan* consisted of two major parts: (a) an introductory statement on Jullien’s critical assessment of the state of education in the different countries of Europe, and his own ideas as to how the ‘incomplete’ and ‘defective’ European education could be improved; and (b) a series of questions which were intended to collect ‘facts and observations’ and ‘destined to furnish material for Comparative Observation Tables’ (Fraser, 1964:31).

Why a Science of Comparative Education?

Like his contemporary French scientific positivist philosopher-sociologist Auguste Comte (1798–1857), Jullien believed that the scientific method could be applied to human and social affairs. As a positive science, therefore, comparative education should focus on objectively determinable and systematically collected facts and observations. A ‘nearly positive science’ of CE, according to Jullien, which in the collection and tabulation of ‘facts and observations’ employed similar methods and techniques/instruments as the positive sciences and the ‘mechanical arts’, would be useful in the reform and improvement of contemporary education throughout Europe. In the introduction to the *Plan*, Jullien averred that both public and private education in the different countries of Europe were ‘incomplete, defective, without coordination ... without harmony with itself in the different physical, moral, and intellectual spheres in which the students ought to be guided’. He attributed the social, political and moral ills of European countries, the corruption and ‘degradation of minds and hearts, which have produced revolutions and wars’, the disorder and the general deterioration of European societies to incomplete and defective education. Consequently, education needed to be reformed and improved. In his own words:

The reform and improvement of education, the true basis of the social edifice, primary source of habits and opinions, which exercise a powerful influence on the entire life, are a need generally felt, as if by instinct, through Europe. It is a matter of indicating the means of satisfying the need in the surest, most efficient, and prompt manner (Fraser, 1964:35).

According to Jullien, the methodological approach by which the defects and weaknesses of education, and generally ‘the condition of education and public instruction in all the countries of Europe’ could be ascertained, would be the drawing up of ‘analytical summaries of information’, collected through a ‘series of questions’—a questionnaire—tabulated in ‘comparative tables of observations’ and classified under ‘uniform headings’ for purposes of ‘comparative analysis’. The responsibility for the collection of such educational facts and observations, for evaluative judgements and for the search of solutions to educational problems ‘would be given to intellectual and active men of sound judgment, (and) of known moral conduct’ (Fraser, 1964:36–37; Kaloyiannaki, 2002:42–43). Jullien articulated this reformative-melioristic value of his ‘nearly positivist’ scientific conception of comparative education as follows:

These analytical summaries of information, on the condition of education and public instruction in all the countries of Europe, would supply successively comparative tables of the present state of European nations in regard to this important aspect. One could judge with ease those which are advancing; those which are falling back, those which remain stationary; what are in each country the deficient and ailing sections; what are the causes of internal defects ... or what are the obstacles to the ascendancy of religion, ethics, and social advancement and how these obstacles can be overcome; finally, which parts offer improvement capable of being transported from one country to another, with modifications and changes which circumstances and localities would determine suitable (Fraser, 1964:37).

A ‘nearly positivist’ scientific perspective in comparative education, as envisaged by Jullien, would also be valuable in other respects. In one respect, it would ‘furnish new means of perfecting the science of education’ (Fraser, 1964:41). In another, it would release comparative study from political influence, the omnipotence of religion, prejudice and despotism (Kaloyiannaki, 2002). And, in still another, it would help in ‘nation-building’, as he argues in the case of a comparative study of education in the 22 cantons of Switzerland. Indeed, according to Jullien, the comparative study of education in the cantons of Switzerland would serve a double purpose: in the first place, it ‘will give birth to the idea of borrowing from one another what they may have which is good and useful in their institutions’; and in the second, it will establish and consolidate ‘the political unity of Switzerland’ by developing ‘a national *Helvetian* mind’ (Fraser, 1964:45–46).

Jullien’s Methodology: The ‘Questionnaire’ and the Indicators of Comparison

Jullien’s comparative methodology could be described as ‘empirico-deductive’ and perhaps ‘qualitative quasi-ethnographic’. It sought to gather data, in Jullien’s words ‘facts and observations’, on education and related questions by means of a questionnaire which consisted of a ‘series of questions’ on six educational areas, namely: (a) primary and common education; (b) secondary and classical education; (c) higher and scientific education; (d) normal education; (e) education of girls; and (f) education, as it related to legislation and social institutions. The collected facts and observations would then be ‘arranged in analytical charts’ or ‘comparative tables of observations’ which would allow for comparative analysis and the deduction of ‘certain principles, determined rules, so that education might become almost nearly a positive science’ (Fraser, 1964:40).

In the *Plan* Jullien identified the educational themes/topics for all six areas for which a series of questions would be posed. However, what he was able to complete was questions for the first two areas, namely, primary and common education and instruction, and secondary and classical education. In each area the questions posed were a set that covered a variety of educational issues, topics and questions. Some of the questions were relatively short, seeking to elicit quantitative data or yes or no answers, while others were relatively long and involved seeking to elicit qualitative

judgements and interpretations. Briefly and selectively, the questions for the first two areas were of the following kind:

1. The first area '*primary and common education and instruction*' included questions on: (a) '*Primary or Elementary Schools*', e.g. number, organisation, maintenance and administration, 'differences among the schools destined for children of different religious faiths', whether they are free or not; (b) *students*, e.g. number, age of admission, enrollment ratios; (c) *directors and primary teachers*, e.g. number, preparation, salaries, possibilities for advancement or retirement; (d) *physical education and gymnastics*, e.g. 'suckling of children, nourishment, clothing, sleep, beds, games, exercises, walks, hygienic care and diet, sicknesses, vaccination, and death rate'; (e) *moral and religious education*, e.g. 'first development of moral sentiments, repression of vicious tendencies, influence of mothers of families, religious instruction whether dry and dogmatic or interesting and appropriate to make a profound impression on the soul, regulations and discipline of primary schools, punishments ... emulation—is it used or not as a necessary motivation?'; (f) *intellectual education*, e.g. 'development of the faculties of the mind, instruction or acquisition of knowledge, first education of the senses and organs, aims and ways of teaching, memory exercises, three principal faculties: attention, comparison, reasoning'; (g) *domestic and private education*, e.g. 'up to what point is the education begun and continued by parents, in the bosom of the family, in harmony or in opposition with the education and instruction given in primary and public schools?'; (h) *primary and common education*—as it is related to secondary education, or to the second stage and with the intentions of children', e.g. 'Is the present organization of primary and common education resting on a basis sufficiently large, solid, and complete to supply children of poor and working classes with all the elementary knowledge indispensable to them to exercise and develop all their faculties?'; and (i) *general considerations*, e.g. 'Is the present manner of bringing up children, up to their seventh or ninth year, the same as in former times? Or rather, in what does the difference consist, between the new and old ways of education?' (Fraser, 1964:53–67).
2. The questions in the second area '*Secondary and Classical Education*' were similar to those in the first. They asked for information about (a) secondary schools (colleges, gymnasia, private institutions and boarding schools), namely, 'number, nature, origin and foundation, organization ... fees'; (b) students, namely, number, age, 'their division into classes', etc.; (c) physical education and gymnastics; (d) moral and religious education, for example, 'Knowledge of God, daily prayers, feeling of benevolence, courage, patience'; (e) intellectual education, for example, 'development of the faculties, acquisition of knowledge or instruction ... teaching aims/methods ... classical books ... exercises to develop the memory, judgment or reason, imagination ... vacations ... letter writing style ... study of laws'; (f) domestic and family education—in its relationship with public education; and (g) 'general considerations and various questions' (Fraser, 1964:67–82).

Jullien's Conception of Comparative Education: A Positive or a Human Science?

Viewed from the vantage point of a positivist empirical-scientific methodology, it could be said, as indeed it has been said, that Jullien's questionnaire is too complex, too long and 'biased' in the sense that 'Jullien's assumptions about the proper goals of education colored the questions he asked' (Noah and Eckstein, 1969:29). Likewise, from the same positivist methodological perspective one might also add that in several parts, the questions in the *Plan* are convoluted and 'leading questions' seeking less to record 'objectively determinable' and systematically collected 'facts and observations', and more to instruct and promote Jullien's own ideas and theories about education. Such evaluative comments would indeed be quite in order, especially on the question of 'biased' and convoluted 'leading questions' which appear quite frequently under the thematic categories of 'moral and religious education' and 'intellectual education'. Here are some selected pertinent examples of such types of questions (Fraser 1964).

Under 'Moral and Religious Education'

- 'Does one restrict religious instruction to teaching and explanation of the catechism, precepts, dogmas, ceremonies, exterior forms? Or does one attempt to penetrate children's souls, give solid internal foundation to their religious belief, to form conscience, to develop and fortify by the double strength of habits and examples, the moral character, true devotion, disposition to *benevolence, tolerance, Christian charity*?'
- 'Does one apply oneself (according to the wise advice of the German philosopher, Basedow) to making children well acquainted with virtue in its beautiful side and with vice in its bad side, so that they may become truly good men and not hypocrites, that is to say, that they not only have their own interests in view, when they do good?'

Under 'Intellectual Education'

- 'What are the aims of education which the children usually receive in primary school? (Does one limit oneself in the majority of schools to reading, writing and arithmetic? Or does one also give a few elementary ideas of *grammar, singing, geometrical drawing, geometry, and land surveying, applied mechanics, geography and history of the country, anatomy of the human body, practical hygiene, natural history applied to the study of land products most useful to men*? All the elements of these sciences, as essentials to each individual in all conditions and circumstances of life, would seem to have to form a part of a complete system of primary and common education, perfectly appropriate to the true needs of man in our present state of civilization.)'
- 'Does one apply the elementary teaching method of arithmetic, practiced with success by M. Pestalozzi in his educational institute; or of any other methods of the same kind, whether in arithmetic, or for other branches of instruction?'
- 'How does one seek to develop and exercise in children, in a progressive and imperceptible manner, first, the power of *attention*, the foremost faculty and

generator of all others; then, the faculty of *comparing* or the simile; finally, *reasoning* (which are the three essential and fundamental faculties of human understanding, according to the distinction established by M. Laromiguiere, in his *Lessons of Philosophy*)?'

If, however, one were to place Jullien's conception of a 'science of education' in the post-Enlightenment broader 'scientific' intellectual historical context, and, further, if one bore in mind (a) Jullien's humanistic cultural background, and (b) as noted above, that Jullien was nurtured in the ideas, spirit and culture of the Enlightenment 'paradigm of modernity', one could perhaps understand his conception of comparative education as 'an almost nearly positive science', i.e. as not a positive science in the strict meaning of the term, as this is shown by the nature of the questionnaire and the indicators of comparison in the *Plan*. Positivism, *stricto sensu*, affirms that 'all knowledge regarding matters of fact is based on the "positive" data of experience', and its all-important imperative is 'strict adherence to the testimony of observation and experience'. As a philosophical ideology, further, positivism is 'worldly, secular, anti-theological, and anti-metaphysical' (http://www.brittanica.com/eb/article9_108682/Positivism). Additionally, according to the *Wikipedia* encyclopedia, as it developed in the second half of the twentieth century, positivism (a) focuses 'on science as a product, a linguistic or numerical set of statements'; (b) insists that at least some of the statements made are 'testable, that is amenable to being verified, confirmed, or falsified by the empirical observation of reality'; and (c) is based on the belief that 'science rests on specific results that are dissociated from the personality and social position of the investigator' (<http://en.wikipedia.org/wiki/Positivism>).

Bearing in mind the above, Jullien's conception of a 'science of comparative education' cannot be said to be consonant with the positivistic scientific conceptions of comparative education that developed in the second half of the twentieth century, e.g. that of Harold Noah and Max Eckstein (Noah & Eckstein, 1969). Nor can it be said that it was consonant with other scientific conceptions of the same twentieth-century period, e.g. those of Brian Holmes (Holmes, 1965), George Bereday (Bereday, 1964), the University of Chicago Functionalist School (Anderson, 1961; Foster, 1960), or indeed the Stanford World Systems School of later years (Arnone, 1982). It can, however, still be said that Jullien's conception of a science of comparative education was consonant with what the French and other Europeans, e.g. the Greeks and the Germans, refer to as 'human sciences', which in certain respects are differentiated, in terms of methodology and subject matter, from the positive and the other empirical-statistical sciences. Two years after the appearance of the *Plan* for comparative education, Jullien published a *Sketch for an Essay on the philosophy of the sciences* where, according to Palmer, 'science was taken to mean mental activity of all kinds, including, applied technology, political and economic treatises, imaginative literature, and the fine arts'. In a 'Synoptic Table of Human Knowledge According to a New Method of Classification' in the same *Sketch*, Jullien classified 'human knowledge' under 'first order' and 'second order' sciences. Under 'first order' sciences he included the physical sciences and practical sciences such as 'agriculture, mining, engineering and healing', and under 'second order', he included 'metaphysical, moral and intellectual sciences, relative to

the mind', history, psychology, natural theology, liberal arts, fine arts, practical morality and education (Palmer, 1993:176–178).

Ideologically, as explained below, Jullien could be characterised as an Enlightenment liberal and an international cosmopolitan humanist educational reformer. The purpose of investigating, in a scientific/*epistemic* way, what he considered to be a defective, morally and intellectually, and an 'incomplete' European education, was to ameliorate/improve it by reforming it along what he considered to be the desirable moral, intellectual and physical educational principles. As quoted above, the Enlightenment liberal humanist Jullien considered education to be 'the true basis of the social edifice, primary source of habits and opinions, which exercise a powerful influence on the entire life' (Fraser, 1964:35). He believed that education can exert a decisive influence on the moral and intellectual 'renaissance' of man, on national welfare and on nation-building (Kaloyiannaki, 2002). His comparative method—the use of the type of questionnaire analysed above—sought to do more than merely collect 'facts and observations'. As Noah and Eckstein have pointed out, Jullien 'was ultimately concerned with problems of diffusing knowledge of education, particularly knowledge of educational innovation'. The same authors have added: 'Influenced as he was by the ideas of Rousseau and Pestalozzi, he wished to encourage a practical, child-centered educational methodology that emphasized, among other things, education of the senses and preparation for life in society, all with a humanitarian emphasis' (Noah & Eckstein, 1969:16). Actually, Jullien wished to encourage a multi-prismatic humanistic education, as indicated by his emphasis in the questionnaire on the moral, the religious, the physical and the intellectual education of 'man', who, according to him, is 'the *subject* on which education acts'. Man, Jullien avers, 'is composed of *three* elements: *body*, *heart*, and *mind*, whose culture and development constitute for him the true means of happiness' (Fraser, 1964:48). It would be relevant to add here that Jullien's *Plan* and the questions asked reflected also the humanitarian influence of the German Count Leopold Berchold, a renowned 'traveler and humanist', and of the Frenchman M. Laromiguiere to whom he refers in the questionnaire in connection with an education that cultivates the 'faculties of the soul' (Fraser, 1964:41, 91, 133–147; Kaloyiannaki, 2002). And, further, that some researchers (Gautherin, 1993; Leclercque, 1999) consider that Jullien's work constructs a *polyphonic* human world; for in the *Plan* Jullien goes beyond Europe and refers to '*mankind as a whole*' (*humanité*), to 'all people', to the 'amelioration of the human being' and to the 'love for mankind', thus giving a universal and humanitarian character to his comparative approach and the propositions for reform (Kaloyiannaki, 2002).

A French Enlightenment Liberal: Liberté, Raison, Education

In the preface to his study on Jullien, titled *From Jacobin to Liberal* (1993), R. R. Palmer wrote:

Born in the year when armed rebellion against Britain began in America, he (Jullien) witnessed the fall of the Bastille as a schoolboy in Paris, joined the Jacobin club, took part in the Reign of Terror, advocated democracy, put his

hopes in Napoleon Bonaparte, turned against him, welcomed his return from Elba, became an outspoken liberal under the restored Bourbons, rejoiced in the revolution of 1830, had doubts about the July monarchy, welcomed the revolution of 1848, and died a few weeks before the election of Louis-Napoleon Bonaparte as president of the Second Republic (Palmer, 1993:ix).

And in a chapter on Jullien as a ‘theorist of education’, the same author noted: ‘In education, as in other respects, he (Jullien) turned from the Jacobin into the liberal. Where he had once seen education as part of the revolutionary process, he came to see it as a substitute for revolution, or as a means by which revolution could be prevented’ (Palmer, 1993:151).

The Enlightenment, R. Freeman Butts, a noted educational historian, has written, ‘was a reaction against the traditional civilisation of the old regime in Europe—against absolute monarchy, closed economic systems, rigid social stratification, religious authoritarianism, an unscientific world view, the doctrine of original sin in human nature, and the domination of intellectual life by medieval conceptions of knowledge’. And further:

Underlying this protest was a growing faith in the powers of man, in science, and in human reason. This age of reason preached the humanitarian faith in progress that man, by taking thought, could reform his institutions as a means of promoting the general welfare. These currents of thought helped to shape the pervasive liberal and democratic ideals that came to mark the heartland of the West (Butts, 1973:307).

To the above, one should add another basic tenet of the Enlightenment, namely, the concept of ‘freedom’. ‘Freedom’ was emphasised by J. J. Rousseau, the eminent modern political and educational philosopher and an Enlightenment thinker who influenced Jullien, but also by an equally eminent philosopher, the German, Immanuel Kant. According to Kant, ‘Enlightenment is man’s emergence from his self-incurred immaturity. There is more chance of an entire public enlightening itself ... if only the public concerned is left in freedom ... freedom to make public use on one’s reason in all matters’ (<http://philosophy.eserver.org/kant/what-is-enlightenment>). Lastly, and of particular relevance here, it should be made explicit what appears to be implicit in the above, that in the philosophy of the Enlightenment, education, pedagogy, ‘politics’ and ‘nation-building’ were closely related.

Jullien’s *Plan* and his other texts on education (e.g. his *General Essay on Education* published in 1808) as well as his many writings on ‘culture’ and ‘civilisation’ reflect certain of the aforementioned key ideas of the Enlightenment. First, as shown in the *Plan* but also elsewhere, Jullien placed great emphasis on ‘reason’ and the related ‘scientific way of knowing’, which, as indicated above, were cardinal tenets of the philosophy of the Enlightenment. In the first number of the newly launched *Revue Encyclopédique*, which appeared in 1819, Jullien wrote: ‘Our new journal should meet one of the needs of our time. Its object is to set forth, accurately and faithfully, the march and continuing progress of human knowledge in relation to the social order and

its improvement which constitute true civilization.’ And in an issue in 1823, he wrote: ‘Our *Revue* is the first and only work to have executed, by periodical publication, the great *Baconian* idea of the *unity of the sciences*, brought together in such a form as to resemble a *universal Congress*, in an *alliance* truly *holy* for advancement of the human mind toward the same moral and philosophical goal in the infinitely varied spheres where it is destined to operate’ (Palmer, 1993:178–181; Davies, 1996:596–598).

A second element in Jullien’s theory of education, which was consonant with the philosophy of the Enlightenment, was his emphasis on the ‘regeneration and perfection of public education/instruction’ (Fraser, 1964:36). Like the French Enlightenment thinkers and the French and English political liberals of that time, Jullien considered public education to be socially and politically important for the production of enlightened and patriotic ‘citizens’, for man’s ‘renaissance’, for progress and national welfare. As Palmer pertinently has observed:

It is evident why Jullien thought of education as an aspect of political or social science. The ideas expressed were not his alone. They may be found, more piecemeal, in the educational plans formulated before and during the Revolution, including those of Talleyrand in 1791, Condorcet in 1792, and a plan endorsed by the Paris Jacobins in 1793. They resemble the ideas of Jeremy Bentham and the emerging “Philosophical Radicals” in England (Palmer, 1993:154).

Still another Enlightenment element in Jullien’s educational ideological repertoire, which reflected the influence of Rousseau and Pestalozzi, was his emphasis on the pedagogical principle of ‘complete liberty in the development of natural faculties or inclinations and the individuality of each pupil’. After visiting Pestalozzi’s school at Yverdon in Switzerland in 1810, Jullien enunciated the following pedagogical principle: ‘The fourth general principle ... consists in allowing a full development of the original faculties and inclinations of each pupil as they reveal and express his true nature. ... The child grows and in a way instructs himself; the teacher is only the external means of development and instruction. ... Education should make each child capable of rising to all perfection that his physical, moral and intellectual nature allows’ (Palmer, 1993:163–164).

An International Educationist/Pedagogue and a Cosmopolitis (World Citizen)

From the 1940s, when Jullien’s *Plan* was accidentally discovered, till today, comparative educationists have credited Jullien with being a pioneer in the development of comparative education; indeed, as noted above, some comparativists have hailed Jullien as the ‘father’ of this modernist *episteme* (science). Generally speaking, however, comparativists have paid relatively little attention to Jullien’s pioneering ideas about international education (IE), a kindred *epistemic* field.

The term/concept ‘international education’ has been plagued by vagueness and a multiplicity of definitions and interpretations concerning its subject matter (Vestal, 1994:13). In the recent literature on it, there is a distinction drawn between international education and comparative education, but also a recognition that the two

epistemic domains are related to each other (Fraser & Brickman, 1968). This is also witnessed by the fact that in the 1960s, the name of the newly founded American-based Comparative Education Society was changed to Comparative and International Education Society (Jones, 1971:22). When the term is used by comparative and international educationists it usually refers to the following activities and concerns: (a) study of the education of other peoples in other countries; (b) educational exchanges and study abroad; (c) technical assistance to educational development in other countries; (d) international cooperation in educational development through international organisations; (e) ‘comparative and cross-cultural studies in a variety of subjects and disciplines’; and (f) intercultural education (Vestal, 1994:14).

Viewed from such an international education perspective, one could, not unjustifiably, refer to Jullien as being a precursor of ‘international education’. His views about, and criticisms of, the state of education at the time referred to the ‘different countries of Europe’, not just to his native France. Also, as he states in the *Plan*, what was needed for ‘the regeneration and perfection of public education’ in Europe was the organisation of a *Special Education Commission* ‘small in number, composed of men in charge of collecting, through their own means and by corresponding associates chosen with care, the materials for a general work on the establishments and methods of education and instruction in the different European states, related and compared under this report’. With a carefully selected staff of international associates, this special international commission would see that ‘analytical summaries of information’ about ‘the condition of education and public instruction’ in all the countries of Europe were collected through the use of a common method, namely, a ‘questionnaire’. The purpose of collecting such ‘analytical summaries of information’ was to evaluate the state of education in each European nation, to determine and explain the ‘deficient and ailing sections’ in each country, and to make suggestions for improvement. Speaking as a theorist of education, but more so as an international educational reformer and pedagogue, Jullien elaborated:

These analytical summaries of information, collected at the same time and in the same order ... would supply successively, in less than three years, comparable tables of the present state of European nations in regard to this important aspect. One could judge with ease those which are advancing; those which are falling back, those which remain stationary; what are, in each country, the deficient and ailing sections; what are the causes of internal defects ... or what are the obstacles to the ascendancy of religion, ethics, and social advancement, and how these obstacles can be overcome; finally, which parts offer improvement capable of being transposed from one country to another, with modifications and changes which circumstances and localities would determine suitable (Fraser, 1964:36–37).

In the *Plan*, in addition to the organisation of a special international commission, he proposed that a *Normal Institute of Education* and similar institutions be established in different areas for the training of ‘good teachers’. The Normal Institute would publish a multilingual *Bulletin* or *General Journal of Education* which would disseminate information for the ‘perfecting of instructional methods’ (Fraser, 1964:39).

Jullien's internationalism in education and more broadly in 'culture', 'knowledge' and 'civilisation' was reflected in other activities and theoretical treatises. As Fraser, quoted above, has noted: 'He (Jullien) travelled extensively, attending international congresses, devoting his time to learned societies, and corresponding with statesmen and educators whose cosmopolitanism sought to evade the confines of nationalism as it consolidated itself in Europe.' Apropos of Jullien's contacts with eminent international figures, Fraser quotes Thomas Jefferson, the American president, who in a letter in 1810, acknowledging receipt of Jullien's *General Essay on Education*, praises Jullien for his 'devotion to international education' (Fraser, 1964:12–13).

The *Revue Encyclopédique*, of which he was founder and editor, published articles, reports, short notices, book reviews and letters on civilisation/culture (letters, literature and the arts) and the sciences in America, Asia, Africa and Europe. In one of the 'letters' to the correspondents and contributors of the *Revue*, Jullien noted that the journal was 'circulated through all countries of the civilized world', and added:

It is not enough for us to be *encyclopedists*; we aspire especially to be *cosmopolites* (world citizens). We would not think our task fulfilled unless each of our numbers presented, in the most complete and accurate way, the state of sciences, letters, arts, intellectual labors and moral improvement throughout the surface of the globe. (Palmer, 1993:180–181)

Lastly, it would be appropriate to mention here that Jullien, the internationalist and the *cosmopolitis* (world citizen), does not only merit Palmer's characterisation of 'apostle of civilisation', he could also, quite justifiably, be called 'apostle of peace'. Perturbed by what he perceived to be 'the dissolution of all religious, moral, and social bonds, extreme corruption, degradation of minds and hearts, which have produced revolutions and wars', Jullien stressed the need for the improvement of education, nationally and internationally, for international cooperation and for peaceful coexistence (Kaloyiannaki, 2002). He became a member of the London-based 'Association of Friends for Peace', and in 1833 in *A Letter to the English Nation*, he wrote:

Our illustrious and learned CUVIER, whose recent death was a loss as keenly felt in England as in France, had rightly judged, in his lofty meditations, that only *comparative anatomy* and *comparative geology* could advance the sciences of anatomy and geology which remained so long in their infancy. Similarly, only *comparative civilization* can speedily advance our present civilization, which still preserves, despite its brilliant and imposing wonders, the deep and afflicting traces of the old barbarism. (Palmer, 1993:205)

Given his views about the value of a reformed European education and pedagogy in the regeneration of European societies and the amelioration of the human condition in general, in the *Letter* quoted above, Jullien could easily have added *comparative education* next to *comparative civilisation* as being of equal significance in the advancement of 'our present civilization'. This ameliorative element, which is salient in Jullien's own 'lofty meditations' as well as in his proposals and activities for the

advancement of 'civilization' and 'comparative and international education', merits additional comment.

A 'Scientific Humanist' Reformer and a Meliorist Comparativist/Internationalist

Historical accounts of comparative education as a modernist *episteme* ('science') have placed Jullien's conception of this *epistemic* area in the first phase of its course of development, which has been characterised as the phase of 'borrowing'. Other nineteenth-century observers of European education who have been placed in this 'borrowing' category of 'comparativists' are the American and European educational reformers mentioned in the introduction to this chapter, namely, Calvin Stowe, Victor Cousin and Horace Mann, about whom more will be said below. The emphasis of 'borrowing' in the nineteenth century, according to Bereday, 'was on cataloguing descriptive educational data; comparison of the collected information was then undertaken in order to make available the best practices of one country for transplantation to others' (Bereday, 1964:7). And, according to Noah and Eckstein, Jullien's *Plan* 'is a prime example of work in comparative education motivated by a desire to gain useful lessons from abroad' (Noah & Eckstein, 1969:15, 21). Behind the idea of 'borrowing', of 'transplantation of best practices' and of 'gaining useful lessons' was the meliorist ideology of improvement.

In the *Plan*, Jullien uses the word 'borrowing' as a likely benefit of comparative analysis, when he talks about applying his 'instrument' and 'observation charts' first to the cantons of Switzerland. In his words: 'The bringing together and comparison of cantons in these respects will give birth to the idea of borrowing from one another what they may have which is good and useful in their institutions' (Fraser, 1964:46). In the same text, Jullien also uses the word 'transpose' in the sense of transferring what is found through comparison to be an improvement in one country, to another. In such a case, however, 'modifications and changes which circumstances and localities would determine "suitable," would have to be made'. So, one could say that behind his notions of 'borrowing' and 'transfer' was one side to Jullien's meliorist ideology which was similar to that of the aforementioned nineteenth-century reformers.

But there was another side to Jullien's meliorism that differentiated him from the other 'borrowing comparativists'. This, simply stated, was that Jullien had definite ideas about the type of education and pedagogy that was needed for the regeneration of European man, civilisation and society. This is patently evident by the types of questions he included in the *Plan*, some of which are quoted in the relevant section above. The regeneration of human society, Jullien averred, could only be accomplished through a 'moral and religious education' as well as an 'intellectual education'. A believer in 'faculty psychology', the dominant psychological theory of the time, Jullien called for an education that would develop 'attention, comparison and reasoning', the 'three principal faculties of the mind'. More important, Jullien implies in the questionnaire, would be moral and religious education, specifically: 'first development of moral sentiments ... religious instruction, dry and dogmatic or interesting to make a profound impression on the soul ... knowledge of God, daily prayers, feeling of benevolence, courage, patience' (Fraser, 1994:60, 63, 71). And in the introductory part

to the questionnaire, he unequivocally declared: ‘It is through the return to religion and morality, it is through a reform widely contrived, introduced in public education, that one can reinvigorate men . . . , it is time to give to the prosperity of nations and to the broad foundation of politics the necessary stability of religion and morality’ (Fraser, 1964:34–35).

Epilogue: Jullien as a Comparative and International Educator

We have no evidence that Jullien’s comparative methodology or his ideas and proposals about comparative and international education as presented in his *Plan and preliminary views for a work in comparative education* were adopted or had any significant influence in the subsequent development of the two related *epistemic* domains. As historians of comparative education, we concur with what Stewart Fraser in his authoritative edition and evaluation of Jullien’s *Plan* wrote back in 1964. Agreeing with the historical judgement of Franz Hilker, Isaac Kandel and Nicholas Hans, three twentieth-century pioneer comparativists, that Jullien ‘was unable to influence the development of comparative education to any great extent’, Fraser added:

While Jullien may not necessarily qualify as the principal instigator or exponent of comparative pedagogy in the nineteenth century his *Plan* remains one of the most important artifacts in the science. Technically, and in fact, Jullien never developed a thoroughgoing comparative methodology in education, nor did he live to see his ideas for institutes of international education become established, but he has been widely identified as one of the first to consolidate these useful ideas into a preliminary draft of such potential magnitude that he cannot be ignored today (Fraser, 1964:117).

The Policy-Oriented and Administrative Meliorist Motif in Comparative-International Education: Victor Cousin of France, and Horace Mann, Calvin Stowe and Henry Barnard of the United States

Jullien’s *Plan* and his other writings that dealt with comparative and international education were among very few such discourses that appeared at the beginning of the nineteenth century. Indeed, Jullien’s *Plan* was rather unique insofar as ‘comparative education’ was concerned. But, as William Brickman, a noted historian of ‘international education’ has noted, by 1900, the ‘meager literature’ on ‘foreign education’, what in German has been referred to as *Auslandspädagogik*, was transformed into a ‘flood of books’ and other writings, e.g. reports, travellers’ or visitors’ observations, journalistic reportages and the like (Fraser & Brickman, 1968:19). This was especially true of the United States, but a heightened interest in *Auslandspädagogik* (education in ‘other lands’) was also manifested in European countries, particularly in England and France.

The period following the French Revolution was one of portentous political, social, cultural and economic changes. According to the already mentioned historian Freeman

Butts, by the middle of the nineteenth century there was a ‘transmutation in the heartland of Western civilisation’ from ‘traditional’ to ‘modern’ ideas, socio-economic and political institutions, and values (Butts, 1973:295). Central to the ‘modernity project’, to use Jurgen Habermas much discussed characterisation of this transmutation, also referred to as ‘modernisation’, was the Enlightenment ideas of reason and the ‘reconstruction of the public sphere in which reason might prevail’, as well as the ‘rational organisation of everyday social life’, of ‘objective science’, of universal ‘morality and law’ (Habermas, 2007).

An important element of the Enlightenment ‘modernity project’ was the reform of education. The rational organisation of ‘national/public education’ was seen as a necessary condition in the reconstruction of the public sphere—the emerging political formation of the ‘nation state’—and the rational organisation of social life (Butts, 1973:301–302). As was the case with Jullien’s interest in comparative education, nineteenth-century European and American reformers, in their capacity as educational administrators and policy-makers in their respective countries, showed an interest in ‘foreign/international education’, mainly, however, for the purpose of what in the aforementioned historical accounts of the development of comparative education has been referred to as ‘educational borrowing’ (Bereday, 1964:7; Noah & Eckstein, 1969:16–21). Jullien’s interest in comparative and international education, as noted above, was partly melioristic in the ‘educational borrowing’ connotation of the term, but purportedly it was also ‘scientific’: the systematic collection of comparative ‘facts and observations’ through a questionnaire, which would permit the comparativist-internationalist ‘to deduct from them certain principles, determined rules, so that education might become almost nearly a positive science’ (Fraser, 1964:40–41). To illustrate this ‘non-scientific’ melioristic, in the sense of ‘borrowing’ international/foreign educational discourses and practices, we have chosen to present the ideas of Victor Cousin of France, Horace Mann, Calvin Stowe and Henry Barnard of the United States.

The French Discourse: Victor Cousin—‘If it is Prussia I Study, it is Always of France that I Think’

Victor Cousin (1792–1867) was a contemporary of Jullien, and like Jullien, an Enlightenment liberal intellectual, but there is no evidence that the two collaborated or communicated with each other. Cousin, according to Palmer, was mentioned as ‘subject’ in Jullien’s *Revue Encyclopédique*, but not as a contributor (Palmer, 1993:180). In his professional career as philosopher-teacher at the Sorbonne, Cousin was attracted to German philosophy, particularly to Hegelian idealism, which, according to Walter Brewer’s authoritative study *Victor Cousin as a Comparative Educator* (1971), Cousin introduced into French philosophy (Brewer, 1971:23–24). It was not, however, only German philosophy that Cousin held in high esteem and sought to introduce into France. Like other contemporary European and, as we shall see later on in this chapter, American thinkers and reformers, Cousin held German public education to be very successful, and worthy of study for the purpose of emulating some of its

characteristics and practices. So, soon after his transformation from philosophy professor to philosopher cum administrator and educational policy-maker during the July Monarchy of Louis Philippe (1830–1848)—he served as a member of the Supreme Council of Public Instruction in Guizot’s ministry and in 1840 for a short time as Minister of Public Instruction—Cousin travelled to Germany to study the German educational institutions and practices. The result of his German tour was his influential report *Rapport sur l’état de l’instruction publique en Prusse* (Report on the state of public instruction in Prussia) (1831) which, according to the American historian E. W. Knight, ‘is among the most important of all the reports on educational conditions in Europe during the second quarter of the nineteenth century’ (Knight, 1930:117–118).

Cousin’s Report on Prussian Public Instruction

The main part of Cousin’s report dealt with aspects of Prussian education that Cousin considered appropriate to his purpose, which was expressed in these words: ‘if it is Prussia I study, it is always of France that I think’ (Brewer, 1971:50). Most of what Cousin considered appropriate for his purpose, he found in a legislative proposal by Privy Councilor Johann Wilhelm Suvern, which he called the ‘Law of 1819’. Cousin commented on the following aspects of the Prussian public system of primary education: the organisation and administration or ‘the government of public instruction’; the training, appointment, promotion, emoluments and ‘punishment’ of primary ‘schoolmasters’; the ‘duty’ of parents to send their children to the primary schools, and of each parish ‘to maintain a primary school at its own cost’; the ‘different gradations (or stages) of primary instruction’, i.e. elementary schools (*Elementarschulen*) and burgher schools (*Burgerschulen*); and the content of school curricula (Knight, 1930).

The Suvern ‘Law of 1819’ could be interpreted as being part of the politico-social side of the already mentioned European ‘modernity project’. As Brewer has written, ‘it was among the last in the series of political and social reforms that were designed to modernize and strengthen the State after the disasters of 1805–1806 had left Prussia dismembered and prostrate at the feet of the French Imperial Army’ (Brewer, 1971:44). The Enlightenment liberal reformer Cousin, like his contemporary Prussian reformers, considered the establishment of a national system of public primary schools as being a basic desideratum necessary for the development of a modern French nation state. In the Germanic-Prussian system of primary education and in the Law of 1819, which he described in glowing terms in his 1831 report, Cousin, then a high-ranking policy-maker, saw a framework for the restructuring of French education and the formation of a national system.

In his report, Cousin identified and commented on several aspects of the legal and institutional framework of the Prussian educational system in the ‘Law of 1819’, which, according to him, could be profitably transferred to France. Among these, three received special attention. One, to which he devoted considerable space, had to do with the provisions and mechanisms, which Cousin called the ‘machinery’ and ‘government’ of public instruction, for the formation of a national system. Specifically, he commented on: (a) the ‘national’ obligation of parents to send their children to the primary schools; (b) the ‘duty of each parish to maintain a primary school at its own

cost'; (c) a decentralised administrative structure, whereby, according to the 'Law of 1819 ... every primary school, in town or country, shall have its own particular management, its own special committee of superintendence'; and (d) maintenance 'in a just and reasonable measure' of the 'ancient' and beneficial union of popular education with Christianity and the church, but 'always under the supreme control of the state, and of the minister of public instruction and ecclesiastical affairs' (Cousin, 1930:130–155, 189–198).

Another aspect of Prussian education, embodied in the 'Law of 1819', that impressed Cousin was the organisation of schooling at a national level. The law provided for 'two stages or gradations in primary instruction, i.e. elementary schools (*Elementarschulen*)' for the 'lower classes' and 'burgher schools (*Burgerschulen, Stadtschulen*)' for the middle-class tradesmen and artisans, followed by a third-stage gradation, the 'gymnasia', for those who wanted 'to enter on a course of practical studies in ordinary life, or scientific, superior and special, or professional, studies at the universities' (pp. 155–156). Cousin also referred to, and commented—rather positively—on, the detailed provisions of the law that pertained to the content of the curricula of the elementary and burgher schools. He noted that both types of schools were to provide a general curriculum consisting of religion and morals, the German language, history, geography, mathematics, physics, gymnastics, drawing and singing. The burgher schools, in addition, were to teach Latin. The gymnasia, on the other hand, were to provide exclusively 'a classical and liberal culture' (pp. 155–164).

The third aspect of the Prussian system of education that received special attention by Cousin was the training of primary 'schoolmasters' and their 'mode of appointment, promotion and punishment'. Here again, Cousin quoted in detail the provisions of the 1819 Suvern Law, emphasising what he did with the aforementioned other aspects of the Prussian system, namely, the care and active role of the state in education (pp. 167–188).

Translated into English and published in England and the United States, Cousin's report on public instruction in Prussia impressed the English and American educational reformers, who in the second quarter of the nineteenth century were actively involved in the development of a national state system of elementary schools (Brewer, 1971:54–57). In America, according to Knight, the educational historian: 'The report served to emphasize the importance of state control of education and the training of teachers in normal schools supported by the state. Its influence is widely apparent, especially in Michigan and Massachusetts.' In England, Knight added, '[t]he *Foreign Quarterly Review* viewed Cousin's report as an incontestable proof, "by the solid and substantial argument of complete practical success", that a system of national education was not visionary, not merely a chimera, "not a phantom of the brain, imagined by dreaming philosophers; but a mode of insuring the elementary instruction of all children, which may be established and maintained not less than any army or navy"' (Knight, 1930:116–119).

The influence of Cousin's report in England and the United States lay more in providing a legitimising force for the educational reform efforts of the times, which sought to establish a national state system of elementary/primary schooling. In his native, France, on the other hand, Cousin's report not only provided a legitimating

rationale for the reform of primary instruction, it actually influenced the enactment of the famous Guizot Law of 1833, which in large part was written by Cousin himself; it was based on his report, and it laid the foundation for the development of a French national system of elementary education (Knight, 1930:116; Brewer, 1971:36; Halls, 1965:20). It should be noted here that Guizot and Cousin, both liberals, became high-ranking political figures and educational policy-makers under the new monarchy—the July Monarchy of Louis Philippe (1830–1848). ‘To liberals’, according to the European historian J. M. Roberts, ‘Louis Philippe was attractive because he reconciled the Revolution with the stability provided by the monarchy’ (Roberts, 1996:352). To Cousin, the post-Revolutionary liberal intellectual, who characterised himself as an ‘eclectic’ thinker, a Louis Philippe constitutional monarchy would combine the best qualities of both monarchy and democracy. As an ‘eclectic’ liberal political ideologist and policy-maker during the July Monarchy, he was to found a philosophy of the middle-of-the-road that meant to offend neither Catholic nor atheist, that would be liberal, proclaiming the principles of the French Revolution, but would be opposed to republicanism, a philosophy that was an apologia for the rule of the ‘upper bourgeoisie’ (Brewer, 1971:30). Cousin’s discourse on education—his policy talk and policy practices—reflected his ideological ‘eclecticism’.

An ‘Eclectic’ Political Liberal and Educational Reformer

Cousin’s ‘eclectic’ liberal educational ideology is reflected both in his discursive text on Prussian education and in the policy text of the Guizot Law, reputedly written largely by Cousin. As noted in the discussion above on Jullien, one of the basic doctrines of the European Enlightenment and the ‘modernity project’ was the reform of political and sociocultural institutions, notably the ‘state’, i.e. the machinery of government, and public education as an ideological mechanism of the state. Cousin, the eclectic liberal of the July Monarchy, advocated that for national regeneration and nation-building, the French state should take a more active role in broadening the popular base for education. As Brewer has written:

He [Cousin] argued that the right to educate was neither the natural right of the individual, nor of a group of individuals sharing a special creed, nor was it a private industry; “it is a public resource”. ... Organized society—the State—by providing a school has the right and the duty to insist that certain conditions obtain: this is the State’s right of supervision (Brewer, 1971:16).

In his report, Cousin lauded the Prussian experience of state-building and the state’s active involvement in the development of a national system of elementary education. After quoting profusely from the Law of 1819, which specified the state’s ‘care’ and involvement in the organisation and provision of public instruction, he eulogised: ‘This law ... omits no topic of interest, and is the most extensive and complete law on primary instruction of which I have any knowledge. It is impossible not to be struck with its profound wisdom ... the Prussian law of 1819 appears to me excellent’ (Cousin,

1930:205–206). It was the 1819 Suvern legislative proposal that Cousin recommended to the French Minister of the Interior that it form the basis for the reform of French primary education (Brewer, 1971:44).

The Guizot Law of 1833, whose objective, as stated by Guizot himself, was ‘the greatest good to be derived from educating the people’ (Brewer, 1971:17), was indeed based on Cousin’s report and the Suvern proposal. It reflected the liberal ideology of both Cousin and Guizot, two active liberal educational reformers during the July Monarchy of Louis Philippe. The main provisions of the Guizot Law, which are relevant for us here, were the following: (a) every commune (and there were more than 30,000) was obliged to open an elementary school to which children from poor indigent families would be admitted free; (b) every *department* was required to establish a normal school to train primary school teachers; (c) elementary education was to be organised hierarchically into two levels, i.e. (i) lower primary level schools—similar to the Prussian *Elementarschulen*—to teach the 3 Rs, French and religion, and (ii) upper/intermediate level schools, similar to the Prussian *Burgerschulen*, for the middle classes, to train for commerce and industry; (d) religious and moral instruction was to be included in both levels of schools; (e) the administrative structure of the system was to be decentralised after the Prussian pattern; and (f) the (liberal) principle of *la liberté d’enseignement* was to be recognised by sanctioning the opening of non-state, i.e. private, institutions (Brewer, 1971:58; Halls, 1965:20; Bowen, 1981:315).

Cousin’s ‘eclectic’ liberalism was also reflected in his views about secondary education and his conception of the ideal school system. In this connection it should be noted that Cousin also inquired into the secondary schools of Prussia and Holland and made some comparisons with the French secondary *collèges*. Among other things, Cousin called for the increase in the number of such schools and the removal of barriers to the establishment of private secondary schools. He suggested that the principle of *la liberté d’enseignement* be adopted for secondary education as it had been adopted in 1833 for primary education, and that private secondary schools, like private primary schools ‘shall be subject to the supervision of the special authorities of public education in all matters that concern morals, discipline and studies’ (Brewer, 1971:89). As to his ideal school system, Cousin, as quoted by Brewer (1971), envisaged a selective class system of post-elementary schools: primary elementary schools for everyone, ‘advanced elementary schools’ for the ‘middle class’, lower-level secondary schools for ‘young people of the middle and upper classes’, and selective upper secondary schools for the ‘upper ranks of society’ (p. 95).

Cousin was a humanist intellectual and a cultural educational reformer. He had a classical humanistic formal education and, as noted above, he was a professor of philosophy who was attracted to German thought, particularly Hegelian idealism. In his report on Prussian public instruction he lauded the provision in the Suvern Law that ‘primary instruction shall have for its aim to develop the faculties of the soul, the reason, the senses, and the bodily strength’, and ‘it shall comprehend religion and morals’ (Cousin, 1930:159). And in the same report, which was addressed to the French Minister of Public Instruction and Ecclesiastical Affairs, Cousin declared: ‘Thank God, Sir, you are too enlightened a statesman to think that true popular instruction can

exist without moral education, popular morality without religion, or popular religion without a church. Popular education, ought therefore to be religious, that is to say Christian' (p. 223). Elsewhere in the report, Cousin talked about the programme of studies in the French secondary schools, the *collèges*. Again addressing the Minister, he expressed his 'zeal for classical and scientific studies', and added: '[N]ot only do I think that we must keep up to the plan of study prescribed in our *collèges*, and particularly the philological part of that plan, but I think we ought to raise and extend it.' He further advised the Minister that the French 'endeavour to rival Germany in the solidity of our classical learning', because 'classical studies are, without any comparison, the most important of all'. And speaking as a humanist, he reasoned: 'for their [classical studies] tendency and their object is the knowledge of human nature, which they consider under all its grandest aspects ... classical studies keep alive the sacred tradition of the moral and intellectual life of the human race' (p. 213).

Cousin's observations and reports about foreign education were not limited to primary education in Prussia. He extended his observations to secondary education in Prussia and Holland, and at the same time he made comparisons between the French and the Prussian secondary schools. In one report, a 'memoir on secondary instruction in the kingdom of Prussia' (1837), he referred to the curriculum of the Prussian *Gymnasien* where there was an 'alliance of scientific with literary studies'. And although, in the report on Prussian primary education, as shown above, Cousin emphasised his zeal for 'classical' and 'philological' studies, in the 1837 Memoir on secondary education, he advised that in the *collège* there could be a 'redistribution and an extension of time' so that 'the ancient humanities and the modern languages, mathematics, and natural sciences would be studied' (Brewer, 1971:91–92). As a corpus of knowledge and a mode of intellectual discipline or a means of training the mind (Cousin, like Jullien, adhered to the psychological theory known as 'faculty psychology' and the associated idea of 'mental discipline'), Cousin's conception of the content of the curriculum of the secondary *collèges*—a general education that combined humanistic with scientific studies—could be interpreted as foreshadowing the ideal of *culture générale* which subsequently dominated French educational thought for a long time (Halls, 1965:2).

Victor Cousin and Comparative-International Education

In historical accounts of the modernist course of comparative education that appeared in the 1960s, Cousin is cited as belonging to a period or 'phase' in the development of the field, which has been conceptualised and interpreted in such terms as 'borrowing' (Bereday, 1964), 'educational borrowing' (Noah & Eckstein, 1969) or 'selective cultural borrowing' (Holmes, 1965; Jones, 1971). Similarly, Brewer in his detailed study *Victor Cousin as a Comparative Educator* (1971) described Cousin's report on Prussian secondary education 'as an example of judicious borrowing' (p. 97). There is indeed evidence to justify such a historical periodisation in the modernist course of comparative education. And in the case of Cousin, in his report on Prussian education, as quoted by Brewer (1971), he averred: 'The true greatness of a people does not consist in imitating nothing from others, but in borrowing everywhere what is good and in perfecting it while appropriating for oneself' (p. vii).

The American Discourse: Horace Mann, Calvin Stowe and Henry Barnard

Interest in European education, particularly in German/Prussian, English and French education, was conspicuously evident in nineteenth-century America. It was salient in the first half of the century, and in the case of elementary schooling during the active period of the common school reform in the second quarter of the century. During this period, many American scholars and educational reformers travelled to Europe in search of ideas and practical lessons that could be helpful to them in their efforts to reform and improve education at home. In this study, we have chosen to write about three well-known and influential educational reformers: Horace Mann, Calvin Stowe and Henry Barnard. Mann was a liberal social and educational reformer, a religious humanitarian, and he served as Secretary of the Board of Education of the state of Massachusetts; Stowe was a professor of classical Greek and sacred literature, and an educational thinker who showed great interest in the reform of education in Ohio; and Barnard was a superintendent of schools in Connecticut, who served as United States Commissioner of Education and for many years published the *American Journal of Education*.

Mann, Stowe and Barnard were actively involved, through word and deed, in the common school movement, itself an integral part of the post-revolutionary republican ideal of education. 'In the century of republican education [from the 1760s to the 1860s]', R. F. Butts, the historian, has written: 'Americans eventually chose the common school, control and supported in common, and embracing a supposedly non-sectarian religious outlook ... their primary concern was to design a universal, free comprehensive system of public schools that would promote modern republican [democratic] institutions' (Butts, 1973:408).

As with the Frenchman Victor Cousin, the three Americans were motivated to study European education primarily for 'melioristic' purposes: to see whether they could learn something that would be useful to them in their reformist efforts to improve American education, particularly primary/elementary schooling. Stowe, for example, was commissioned by the state of Ohio to collect, while in Europe, 'such facts and information as he may deem useful to the State [Ohio] in relation to the various systems of public instruction and education' (Knight, 1930:248). And, as R. B. Downs, one of Mann's biographers, quoting Mann has written: 'the celebrity of institutions in foreign countries had attracted his attention, filling him with "an intensive desire of knowing whether, in any respect, those institutions were superior to our own; and if anything were found in them worthy of adoption, of transferring it for our improvement". ... Of first importance to Mann was to find "beacons" to terrify as well as lights to guide' (Downs, 1974:88). Also, as with Cousin, the Americans had high praise for the German/Prussian common school education, particularly the active role of the state, and the governance of schooling. All three were especially impressed by the Prussians' success in their efforts to establish a system of what Barnard called 'true national education' (Barnard, 1872:365). All three also commented favourably on the Prussian teachers and the internal pedagogical aspects of schooling. Mann, especially, was impressed by the methods of teaching, the school discipline and generally by what he felt was a humane

classroom atmosphere in the Prussian schools (Downs, 1974; Holmes, 1965). Stowe praised the non-Republican government of the ‘unostentatious’ monarch Frederick William in that it ‘repeatedly and strenuously insisted in all the laws pertaining to education, to awaken a *national spirit*—to create in the youthful mind a warm attachment to his native land, and its institutions’ (Knight, 1930:255). And, like Jullien and Cousin, all three Americans made special reference to the emphasis the Prussian schools placed on moral and religious instruction.

The American Liberal Republicanism/Reformism and the Comparative-International Education Melioristic Discourse

From a political ideological standpoint, Horace Mann, Calvin Stowe and Henry Barnard could be characterised as liberal democratic-republican thinkers and social activists who espoused the principles of nineteenth-century ‘liberal republicanism’ also referred to as ‘classical liberalism’ with its emphasis on freedom, liberal democracy and popular education. Referring specifically to Horace Mann’s republican ideology and its relationship to public education, Lawrence A. Cremin, the distinguished American historian, has written:

Mann understood well the integral relationship between freedom, popular education, and republican government. ... A nation cannot long remain ignorant and free. No political structure, however artfully devised, can inherently guarantee the rights and liberties of citizens, for freedom can be secure only as knowledge is widely distributed among the populace. Hence, universal popular education is the only foundation on which republican government can securely rest (Cremin, 1957:7).

Unlike Jullien’s, the American discourse was only tangentially about comparative education, and like Cousin’s, it was more about foreign education, or to use Fraser’s and Brickman’s terminology, it was *Auslandspädagogik* (Fraser & Brickman, 1968:19). Like the francophone discourse (Cousin’s and what Jullien wrote about foreign education in the *Plan* and elsewhere), the American discourse was descriptive, reportorial, ‘ahistorical’ and for the most part non-comparative, non-systematic and non-analytic, except with some qualifications in the case of Henry Barnard’s studies.

The comparative educational historian cannot but be impressed by Barnard’s comprehensive account of the history, organisation, administration, studies, curricula, teachers and pedagogy, discipline and statistics of public schools of every grade and for all classes, as well as other institutions of general education, in different countries (Barnard, 1872). In his commentary on Barnard’s approach and studies, Holmes has observed that ‘unquestionably’ Barnard’s ‘approach to comparative education was largely historical and descriptive’, and his aim to produce an ‘encyclopaedia of education ... was virtually achieved’ (Holmes, 1965:14). Noah and Eckstein have also commented on Barnard’s encyclopedism, but they were more critical of his approach than Holmes. According to them, Barnard ‘saw merit in the indiscriminate and even unsystematic recording and republication of *all* that was available’ (Noah & Eckstein,

1969:25–26). It is appropriate to characterise Barnard's approach as being descriptive, but in our interpretation, it is inappropriate to characterise it as 'unsystematic' or 'indiscriminate reporting'. It would also be appropriate to characterise Barnard as a good 'chronicler' or a good 'educational narrator' or 'educational ethnographer', rather than a good 'educational historian'; his historical accounts of education in the several European countries lacked the elements of historical interpretation and contextual explanation, two basic desiderata of any historical *episteme*/science. Nor can Barnard, and we might add Mann and Stowe, strictly speaking, be described as 'comparativists', as Holmes as well as Noah and Eckstein have argued (Holmes, 1965; Noah & Eckstein, 1969). Barnard, in several of his studies of education in European countries, always wrote about the 'history' or the 'historical development' of education and instruction in the particular countries, or about the 'educational history' of each state, e.g. Prussia (Barnard, 1872:335). But his historical accounts lacked the element of interpretation and contextual explanation, which are basic desiderata of any historical *episteme* ('science'). Barnard's historical accounts can at best be characterised as historical narratives or 'chronicles'. One, however, should not underestimate the value of good descriptive chronicles or narratives in studying foreign education even today, and in our judgement Barnard's 'educational histories' deserve high praise, especially when one considers the times when they were written.

Coda—on Meliorism

Finally, there were two other elements in the nineteenth-century American 'comparative-international discourse', as examined above, which differentiated it from the European, as was exemplified by the aforementioned francophone Victor Cousin and even Marc-Antoine Jullien. The first, simply stated, was that the Americans were more disposed to look critically at the European educational experience than the Frenchmen. The second, which is worthy of some additional comment, pertained to their 'meliorism', an overriding consideration/purpose of all the nineteenth-century precursors of 'comparative-international education', and one we may add which, *ab initio*, has been, to a degree more or less, germane to what may be called the 'comparative epistemic *problematique*'.

Meliorism, from the Latin *melior* (better), can be understood as inquiry with the objective of improvement. As indicated in this chapter, the 'objective of improvement' was germane to all the nineteenth-century inquiries into foreign, in this case European, systems of education. We noted that Jullien talked about collecting 'facts and observations' that would help in the reform of education for the betterment of European societies and, internationally, of the human condition; Cousin, Mann, Stowe and Barnard talked about the improvement of national education in their own countries. We have also noted that well-known comparativists like George Bereday, Harold Noah and Max Eckstein in the United States, and Brian Holmes in England have characterised all of the nineteenth-century French and American observers and students of European education, mentioned here, as belonging to the 'borrowing' or 'selective cultural borrowing' phase in the development of comparative education. According to these later comparativists, the nineteenth-century precursors were motivated 'by a desire to gain

useful lessons from abroad' and to 'borrow', transfer or 'transplant' useful ideas and practices for the purposes of educational improvement (Noah & Eckstein, 1969; Bereday, 1964). The 'borrowing' aspect/dimension of meliorism is clearly evident in Jullien and Cousin. But it is not as clear in the case of the American nineteenth-century meliorist reformers. It is, of course, the case that, like the Europeans, the American policy-makers and administrators were motivated 'by a desire to gain useful lessons from abroad', but not for the purpose of 'educational borrowing' or 'transplantation' as understood by Jullien and Cousin. It would be more accurate to say that the American meliorists sought 'lessons' from abroad to use as legitimating rationales for the reform of national public education in the United States.

FORGOTTEN MEN, FORGOTTEN THEMES: THE HISTORICAL-PHILOSOPHICAL-CULTURAL AND LIBERAL HUMANIST MOTIF IN COMPARATIVE EDUCATION

Andreas M. Kazamias

The Historical-Philosophical-Cultural and Liberal Humanist Comparative Discourses

Historical accounts of the development of Comparative Education (CE) as a field of study trace its beginnings to several discourses—policy talk and policy practice—in Europe and America in the nineteenth century. At the beginning of the century (in 1817), the Enlightenment Jacobin-turned into liberal thinker Marc-Antoine Jullien de Paris (Palmer, 1993: 151) published his *Esquisse et vues preliminaries d'un ouvrage sur l'education compare* (*Plan/Sketch and preliminary views for a work on comparative education*), often taken to mark the beginning of CE as a modernist *episteme*. In this short book, Jullien sought to construct an empirically based 'positive science' of CE, one that would provide 'non-arbitrary' and 'non-capricious' knowledge for 'the reform and improvement of education' (Fraser, 1964: 40–41). In the ensuing years—by the middle decades of the century—another type of comparative discourse became dominant that was quite different from that of Jullien, in a number of reports on education in continental Europe, written for the most part by educational administrators, educational policy-makers or policy-advisers, social thinkers and social reformers, e.g. Horace Mann, Calvin Stowe, John Griscom and Henry Barnard from the United States, Joseph Kay and Matthew Arnold from England, and Victor Cousin from France. In observing and studying continental European systems of education, e.g. the German/Prussian, the French, the Italian and the Swiss, the overriding consideration of these 'comparative educationists' was 'lesson learning' and 'borrowing': to see what useful lessons could be drawn from such observations in order to press for educational reforms at home (Jones, 1971: 45). In general, as we have noted elsewhere, these early comparative education discourses were: (a) mostly 'reportorial-descriptive'; (b) they were governed by a lesson-learning utilitarian-instrumental purpose in order to reform education at home; and (c) they were melioristic in that the authors were mainly concerned with the improvement of education based on certain *a priori* values as to what a good educational system is (Kazamias & Massialas, 1965: 2).

In the second half of the nineteenth century comparative education discourses began to take a different epistemic form/trajectory. Beginning in mid-Victorian England with

Matthew Arnold—the poet, the literary critic and the apostle of Eurocentric humanistic culture—and in the United States with William T. Harris—the Hegelian philosopher-educator and US Commissioner of Education—and culminating in England with Michael Sadler—Eurocentric classical humanist, historian-comparative scholar and liberal educational reformer, one observes the adumbration of what may be called the ‘historical-philosophical-cultural and liberal humanist’ motif in CE that came to dominate the field until the middle decade of the twentieth century. In the Anglo-Saxon world, the ideas of Matthew Arnold and more so those of Michael Sadler exemplify best the nineteenth century nascent ‘historical-philosophical-cultural’ CE discourse.

Matthew Arnold and, as we discuss in the sections that follow, Michael Sadler, both nurtured in the nineteenth century hegemonic classical humanistic *paideia*, were critics of the Victorian polity, society and culture. Arnold, in particular, was a caustic critic of the Victorian ruling aristocracy, the uncultured ‘barbarians’, and the undemocratic political ideology of laissez-faire liberalism—with its emphasis on individualism, voluntarism and non-state interference—which he called the creed of the Philistines, the people who did not possess ‘sweetness and light’ or ‘culture’. Liberalism, according to him, connoted ‘democratic equality’ or ‘social liberty’, rather than the cult of individualism or the rule of one class. Culture, his favourite word, and the object of education, could not be achieved without the intervention of the State, which he interpreted as ‘the representative acting power of the nation; the action of the State is the representative action of the nation’ (Nash, 1966: 78; Kazamias, 1966: 103). In continental Europe, particularly in France, Arnold saw liberal democracy as ‘the growing power’ which he attributed to ‘the action of the French State’ (Nash, 1966: 61).

State action and control, according to Arnold, were responsible for the great development of popular/primary and secondary education in continental Europe, particularly in France and Germany. And he had high praise for the French Lyceea, the secondary schools that were founded and maintained by the State since the days of Napoleon. In his famous essay ‘A French Eton’, Arnold commented favourably on the Lyceum of Toulouse paying particular attention to the ‘programme of studies’ which, in addition to the heavily classical content (Latin and Greek), included ‘some instruction in natural science’ and modern subjects (e.g. history, geography and modern languages), and the study of French ‘the mother tongue’ (Nash, 1966: 113–115).

As with the comparative discourses that preceded him, Matthew Arnold, as Her Majesty’s Inspector of Schools, examined continental educational systems to see whether he could learn something that would help solve educational problems at home. But, unlike the mainly descriptive discourses of the nineteenth century educational administrators and policy-makers, Matthew Arnold’s educational observations were contextualised in the sense that they were interpreted by being placed within the national political and cultural contexts of the European states. Viewed from this perspective, Arnold’s comparative approach could be described as quasi-historical, liberal-humanistic and cultural, a harbinger of the twentieth century ‘historical-philosophical and liberal humanist motif of CE that was associated with Michael Sadler, Isaac Kandel, Nicholas Hans, Robert Ulich, and Friedrich Schneider, to name its best-known exponents, and with V. Mallinson, P. Sandiford, A. H. Moehlman, J. F. Cramer and G. S. Browne (Mallinson & Sandiford, 1918; Moehlman, 1963; Cramer & Browne, 1956/1965).

The Historical-Philosophical-Cultural and Liberal Humanist Motif in Comparative Education: Michael Sadler, Isaac L. Kandel, Nicholas Hans and Robert Ulich

There were commonalities as well as variations in the historical—philosophical and liberal humanist approaches to the comparative study of education as represented by Sadler, Kandel, Hans and Ulich. As analysed below, both the commonalities and the variations can be attributed to these comparativists' disciplinary/*epistemic* and socio-cultural background, the times and places in which they lived, their professional activities and the types of questions they asked. In the sections that follow I shall first identify the elements that are common to all these comparative scholars. Subsequently, the variations will be brought out as I analyse in greater detail the thought of each of these doyens of comparative education.

Epistemological, Ideological and Methodological Commonalities

- (a) Comparative education is not an empirical or a positivistic 'social science'. It is a 'human science' in the broad meaning of the term 'science' as signified by the German word *Wissenschaft* and the Greek equivalent *Episteme*. As interpreted by Hans, Kandel, Ulich and I may add, Schneider, the term comparative education (CE) was nearer to the German *Vergleichende Erziehungswissenschaft* than the French *Education Comparée* or the American comparative education. It was analogous to such studies as Comparative Religion, Comparative Law and Comparative Anatomy in that 'comparisons were not limited to contemporary actual situations but were extended to the study of the origin and evolution of present systems of law, religion or language'. Also, according to Hans, the German usage included the philosophy of education as well (Hans, 1959: 443). And again: 'Comparative Education as an academic discipline is just on the border line between humanities and sciences and thus resembles philosophy, which is the formulation of both' (Hans, 1959: 299).
- (b) Comparative Education is an explanatory/interpretive *episteme*, that aims at 'understanding' and 'interpretation' of how national systems of education developed to be what they are, not a predictive or a policy-oriented or practical/applied social science. Kandel, Hans, and Ulich wrote about or narrated past events, but more significantly, they searched for forces and factors (political, social, economic and cultural) which, in their judgement influenced, produced, 'caused', or 'determined' problems, similarities and differences in national systems of education, or aspects of it (structures, policies, practices, etc.). Generally they sought to show that national systems of education were the outcome of particular and 'unique' constellations of social, political, economic and cultural forces, factors and traditions. As such, they were concerned less with generalisations and 'theories' and more with interpretation/explanation of temporally and spatially located particular educational phenomena. As Kandel averred in his *Comparative Education* (1933): 'The chief value of a comparative approach to such problems [of education] lies in an analysis of the causes

which have produced them, in a comparison of the differences between the various systems and the reasons underlying them, and finally, in a study of the solutions attempted' (Kandel, 1933: xix).

- (c) The above should not be interpreted as implying that these comparative scholars envisaged CE to be a pure intellectual knowledge producing *episteme*, without any 'instrumental', 'utilitarian' or 'melioristic' benefits. Although they were primarily historian-intellectuals 'intent on explanation rather than activists in the field of educational policy-making', they were also 'historical-meliorists': they believed that by studying the educational system of other countries, a broad philosophical outlook/attitude and the necessary insights could be developed that would help understand better and improve education in one's own country (Noah & Eckstein, 1969: 57; Kazamias & Massialas, 1965: 3).
- (d) The epistemic units of comparative study and analysis are nation states and national systems of education: English, German, French, American, Russian. In their interpretation and explanation of national systems of education the main aim is explaining and 'understanding' how national systems of education developed the way they did, and why they exhibit the characteristics and peculiarities that they do. In their historical explanations and interpretations of variations in national educational patterns and practices, these historically oriented comparativists considered 'nationalism', national traditions, national political ideologies and 'national character' to be 'determining' factors. As Kandel noted in his 1933 study: 'Comparative education would, accordingly, be meaningless, unless it sought to discover the meaning of nationalism as it furnishes the basis of educational systems', and 'each national system of education is characteristic of the nation which created it and expresses something peculiar to the group which constitutes that nation; to put it another way, each nation has the educational system that it desires or that it deserves' (Kandel, 1933: xxiv). Earlier (1900), Michael Sadler had stated: 'A national system of education is a living thing, the outcome of forgotten struggles and difficulties and of battles long ago. It has in it some of the secret workings of national life. It reflects, while seeking to remedy, the failings of national character. By instinct it often lays special emphasis on those parts of training which the national character particularly needs' (Sadler, 1900). Later (1949), in the same vein, Nicholas Hans declared: 'National systems of education as well as national constitutions or national literatures are the outward expression of national character and as such represent the nation in distinction from other nations' (Hans, 1949: 9). And, according to Mallinson (1957), education 'is a function of national character', which he defined as 'the totality of dispositions to thought, feeling and behavior peculiar to and widespread in a certain people, and manifested with greater or less continuity in a succession of generations' (Mallinson, 1957: 14).
- (e) As an explanatory/interpretive *episteme* and not an empirical social science, its data base and modes of investigation are more qualitative than quantitative. Sadler, Kandel and Hans explicitly eschewed quantitative statistical analyses of educational systems or problems on practical but, more importantly, on epistemological/intellectual grounds. In the opening years of the twentieth century,

Michael Sadler argued against ‘purely statistical inquiries’ in education, because the interpretation of educational data must be made ‘in the light of the value system of each country’ (Holmes, 1965: 16). In his seminal text *Comparative Education* (1933), Kandel wrote:

There are at present time two outstanding trends which can be distinguished in the study of education. The first is the attempt to make education scientific and objective by the application of statistical methods—all education must have an affirmative value which can be proved and verified statistically.... Assuming that the methods of statistical tests and measurements have become sufficiently established to be reliable, all that can be claimed for them is that they can measure results, but they cannot define aims and purposes of education; they may formulate norms, and that only in a limited range of activities, but they cannot set up qualitative standards (Kandel, 1933: xxiii).

Writing in the 1950s, Hans noted that in the United States during that period, researchers employed statistical methods in their comparative investigations of certain aspects of the educational system of the 48 states (e.g. financing, salaries of teachers, compulsory attendance, percentage of college students in an age group, and teacher/pupil ratios). Americans also widely used the method of quantitative comparison ‘based on psychological tests and IQ’ to compare ‘various “racial” groups of immigrants by their IQ with the inevitable conclusion that Nordic groups are more desirable than the Slavs or Italians’. As to the first type of investigation, Hans noted that ‘within the limits of one country, where the terminology is identical and social conditions do not greatly vary statistical methods may be employed with profit and may lead to some valid conclusions’. But when this method is used for international comparisons ‘we meet with so many difficulties that it is doubtful whether we can arrive at any valid results’. Commenting on the value for Comparative Education of both methods—the statistical and the psychological—Hans concluded that they both ‘need a careful revision and standardization before providing a sure guide for Comparative Education’. Until this was done ‘comparisons should be mainly concerned with quality of education’ by which he meant ‘not so much efficiency or curriculum as the whole atmosphere and structure of the school system’ (Hans, 1959: 447).

- (f) Sadler, Kandel, Hans, Ulich, Mallinson, and we might here add Matthew Arnold, their intellectual predecessor, were all nurtured in the European classical humanistic educational tradition and liberal humanist values. Ideologically, they were all internationalists and ‘liberal democratic humanists’, not laissez-faire liberals. Not only could Comparative Education be a positive force for the improvement of education and the fostering of ‘internationalism’; it could also be a positive force for the development of ‘liberal democracy’ and ‘democratic citizenship’. Their work was infused with ‘Eurocentric’ and Western liberal democratic ideas and liberal-humanist values about the polity and the state-system of education, about the nation state and civil society, about the role of the individual and the State and about ‘liberty, equality and fraternity’. And in the spirit of the ‘Enlightenment project’, all of them had an abiding faith in the

idea of progress through enlightenment and education. Speaking about Sadler and the other university men involved in the University Extension work that had to do with the ‘labouring classes’, the historian Brian Simon wrote: ‘All shared a liberal-humanist outlook: education was good for its own sake, the workers deserved all that the university could offer in the form of extra-mural teaching; education would spiritualise their lives. This implied a desire to provide a broad, humane, comprehensive, above all, an impartial education, one rising above, and so enabling students to rise above the ephemeral and material struggles of the time’ (Simon, 1965: 305).

- (g) Generally, these historically oriented comparativists were predominantly ‘idealists’; they paid more emphasis on the power of ideas, ideals and forms in their historical explanations of educational systems and problems. Clearly they were not Marxists, in any ideological and intellectual meaning of the term. Although they included economic considerations among their historical explanatory ‘forces and factors’, the relative emphasis they assigned to them was less than the emphasis they place on cultural, intellectual, valuational, religious, ‘spiritual’ and ideological considerations. ‘What do we compare?’ Kandel asked in 1956, to which he responded: ‘The answer should be the comparison of ideas, ideals and forms’ (Kazamias & Schwartz, 1977: 154–155).

Epistemological, Ideological and Methodological Variations

Michael Sadler: Historical-Cultural Comparativist, Liberal-Humanist Reformer

Michael Sadler was a pioneer of what we have called the ‘historical-philosophical-cultural and liberal humanist motif’ in CE. Intellectually, ideologically and methodologically he personified all of the aforementioned characteristics of this motif. But in Sadler the intellectual historian can also detect some interesting particularities/variants, both of which—commonalities and particularities—as shown below, can be illuminated by looking at his educational background, his professional career and the historical context of late Victorian England.

Sadler was nurtured in the classical humanistic literary tradition of Rugby Public School and Trinity College, Oxford. As I had noted in an earlier study, this type of education left a lasting imprint on his educational ideology as an educational reformer: ‘In his reports written after 1902 on behalf of various local education authorities, it is clear that Sadler considered a humanistic literary type of education as the distinctive characteristic of liberal education and *mutatis mutandis* of secondary schools’. According to Sadler, I further added: ‘the dominant aim of secondary education should be first and foremost to humanise through the real and vivid teaching of the humanities, and then to impart efficiency for life as it has to be lived’ (Kazamias, 1966: 140–141).

Sadler’s intellectual and reformist activities can be illuminated further by looking at the state of England—English polity, society and culture—vis-à-vis continental Europe and the United States, and the prevalent intellectual and ideological currents at the end of the nineteenth century and the beginning of the twentieth century. During

the heyday of laissez-faire liberalism in the nineteenth century, England was 'the forge of the world, the world's carrier and the world's entrepot' (Knowles, 1921: 139). In the eyes of their European rivals, the English had discovered the secrets of economic prosperity, political stability and the 'philosophy of happiness'. But by the end of the century, all this had undergone significant transformations. Germany in Europe and the United States of America had challenged England's industrial and commercial supremacy. Similarly, by that time England's 'utilitarian philosophy of happiness', associated with Jeremy Bentham and John Stuart Mill, and laissez-faire liberalism had ceased to occupy the intellectual position it did earlier, or to furnish the legitimating rationale for political, social and educational reforms. Instead, the eyes of British thinkers, statesmen, social and educational reformers had turned to Europe, and especially to Germany, which at that time was dominated by the 'idealist' philosophy of Kant and Hegel. At Oxford, T.H. Green, reputed/considered to be the most influential teacher at Oxford since John (Cardinal) Newman, had inaugurated an 'idealist' philosophical tradition that went by the names of 'Neo-Kantism', 'Neo-Hegelianism', 'Idealism' or 'Neo-Idealism', and which, in addition to Green, included such other influential thinkers as F. H. Bradley, B. Bosanquet and J. M. E. Mc Taggart. Drawing their inspiration from Plato and Aristotle, as well as from Kant and Hegel, these British 'idealist philosophers', unlike the utilitarians and the 'laissez-faire liberals', conceived of freedom, not in abstract negative terms, but in more positive terms, and of the State as a positive actor in society (Kazamias, 1966: 108–109).

The significance of the above for us here is that Sadler, the historian-intellectual and educational reformer, was influenced by the German-inspired Oxford idealist philosophy, and he attributed the phenomenal commercial and industrial expansion of Germany to the efficient organization and administration of the German system of education, the nature/content of instruction, and generally to the 'spirit' that gave it 'a life', the 'intangible, impalpable, spiritual force' which upheld it and accounted for its success and 'practical efficiency'. Apropos of the above, as an educational reformer Sadler deviated ideologically from the laissez-faire individualistic social philosophy that characterised Victorian England and was nearer to the New Liberalism that developed in the late Victorian period. Although 'freedom' had remained the essential ingredient of the Liberal creed, the New Liberals, like the aforementioned English idealist philosophers interpreted 'freedom' not entirely in negative terms as 'freedom from constraint', but in more positive terms. In matters of social and educational policy the positive conception of freedom meant 'state interference' in social, political, economic and educational reform. Although he would not sacrifice the freedom and individualism of the English educational system to the 'large measure of State control' that obtained in Germany, Sadler sought to explore, in his own words, 'that debatable territory between Individualism and Socialism' (Sadler, 1898: 95).

Like the other historical-cultural and liberal humanist comparative scholars, e.g. Kandel, Hans and Ulich, Sadler was a 'historian-intellectual' and a meliorist. But unlike them he was also an educational statesman, and an active educational reformer. His reports/studies on foreign systems of education (European and American) prepared on behalf of the newly created Office of Special Inquiries and Reports, an 'educational intelligence office', as Sadler its director called it, were 'historical' and 'comparative,

as he understood the intellectual and methodological contours of the two *epistemes* to be in the waning years of the nineteenth century and the opening years of the twentieth century. In his studies of Prussian and German secondary education, for example, he explicitly stated: ‘The present results have been obtained by the labour of several generations. Their full significance can only be understood in the light of their history’ (Sadler, 1898: 246; also see Noah & Eckstein, 1969: 45). And in his comparative essay ‘The Unrest in Secondary Education in Germany and Elsewhere’ (1902) he wrote:

Educational thought all over the world is taking much more account of social environment in its analysis of the functions of schools in national life. Hence there is much more sympathy with the customary English view of education. But ‘social environment’ includes not merely material conditions of domicile, food, clothing, etc., but spiritual, moral, and intellectual surroundings, and the power of tradition. (Sadler, 1902: x–xi)

And like the other ‘historian-intellectual’ comparativists, in his own historical-contextual studies Sadler also included such explanatory cultural forces as ‘national temperament’, ‘national sentiments’, ‘national traditions’, ‘national aims and ideals’, and ‘national character/characteristics’. Thus, in these studies of foreign systems of education, Sadler was consistent, intellectually and methodologically, with his dicta in the famous Guilford lecture of 1900 that ‘in studying foreign systems of education we should not forget that the things outside the schools matter even more than the things inside the schools, and govern and interpret the things inside’ (Sadler, 1900/1964: 310). But in addition to these non-school contextual-explanatory social-cultural factors, Sadler also talked about the ‘inner life’ of a national system of education and about ‘intangible, impalpable spiritual forces’, which differentiated his approach from some of the other ‘historian-intellectual’ comparativists that followed in the twentieth century. In his own, often-quoted words:

[E]ducation is not a matter of schools or book learning alone. Therefore, if we propose to study foreign systems of education...we must also... try to find out what is the intangible, impalpable, spiritual force which, in the case of any successful system of Education, is in reality upholding the school system and accounting for its practical efficiency... A national system of education is a living thing, the outcome of forgotten struggles and difficulties, and ‘of battles long ago.’ It has in it some of the secret workings of national life (Sadler, 1900/1964: 309–310).

Another Sadlerian particularity was that Sir Michael was what may be called an ‘English new liberal humanistic educational reformer’. As early as 1884 he engaged in a successful campaign for the development of adult education through University Extension; he served as an active member on the famous Royal Commission on Secondary Education (the Bryce Commission) of 1894–1895 and was reputed to have been ‘the chief author of the report’; he was instrumental in setting up the Office of Special Inquiries and Reports of which he served as Director from 1895–1903; in

some of the reports on foreign systems of education and those written on behalf of various English local education authorities, he included recommendations for reform; from 1911–1923 he served as Vice-Chancellor of the University of Leeds; and in 1907 he published his plan for ‘A Bureau of Education for the British Empire’ (Kazamias, 1966: 28–29; Jones, 1971: 49–50). It is patently clear, therefore, that as J. H. Higginson, one of his biographers has pointed out, Sadler viewed comparative education, not only as a scholarly intellectual activity, but also as ‘an agency of reform’. Although in his Guildford lecture he stressed that ‘the practical value of studying... the working of foreign systems of education is that it will result in our being better fitted to study and to understand our own’, and that such study will in turn enable us ‘to enter into the spirit and tradition of our own national education’, as the Director of the Office of Special Inquiries and Reports 3 years later he wrote:

The chief work of an educational intelligence office... is to collect, summarise, and publish various kinds of educational experience, with a view to (1) getting what is sound and true from a number of discrepant opinions; (2) informing the nation how it stands in regard to educational efficiency as compared with other nations; and (3) promoting, as far as possible, general consent and agreement as to the wisest and most fruitful line of development in national education (Higginson, 1961: 289).

These intellectual, ideological and methodological elements Sadler bequeathed, to a degree more or less, to the historical-cultural and liberal humanistic twentieth century comparative education scholars, and notably to his student Isaac Kandel, who dominated the field until the middle decades of the twentieth century.

Isaac L. Kandel: Historian, Philosopher, Humanist Comparative Educator

In 1933, Isaac Kandel, a European Jewish intellectual and a product of the Eurocentric liberal humanistic culture, who emigrated to the United States at the turn of the twentieth century, and as a university professor in the United States attained international reputation as an educational historian-philosopher-comparativist, published an educational book entitled *Studies in Comparative Education/Comparative Education*. It was a seminal text in a new educational *episteme*, in which Kandel sought to define the epistemological, methodological and ideological contours of comparative education, to identify its subject matter, and to discuss its value in the modern world. *Comparative Education* was destined to become a landmark and in the ensuing years Kandel became a dominating figure in this fledgling/new educational discipline. In the mid-1950s, Kandel published a sequel to this pioneer study, entitled *The New Era in Education* (1955), in which he re-iterated his approach to comparative education as well as its subject-matter and value.

In the 1960s, the fast-growing field of CE developed in different epistemological and methodological directions, and Kandel’s approach was criticised by, among others,

the present writer (Kazamias, 1959, 1961, 1965), and by some it was considered to be *passé*, bordering on ‘mysticism’ or, at best, ‘non-scientific’ (Holmes, 1965; Noah & Eckstein, 1969; Epstein, 1970: 313, 314). Nevertheless, Kandel continued to be widely cited and read, and revered as the grand pioneer of this modernist educational *episteme* (Kazamias & Schwartz, 1977). In ‘memorials’ to Kandel, when he died in 1965, George Bereday, at the time editor of the *Comparative Education Review* and a leading figure in the revival and reconstruction of the field, eulogised: ‘The passing of Professor Isaac L. Kandel has cast a sombre shadow over the field of comparative education...Professor Kandel belongs to the generation of universitarian humanists who will not be easily reproduced in our age of more technological, more rushed, more narrowly specific applications. Nothing can match the towering stature of that passing generation and the inspiration they evoked’ (Bereday, 1965: 249).

And quite perceptively, Bereday had this to say about Kandel’s epistemological identity:

He [Kandel] was a humanist...he was neither a scientist nor a semantic pedant. He believed in intuition...He was a humanist, a man of letters, a cultivated European-American...He was unmistakably a Jew. His Judaism was of the finest and the staunchest... Now he is gone, a towering landmark, an ivory tower perhaps, but better a beacon in what by efforts of others has become a surging tide... We mourn him for we are his children and grandchildren. (Bereday, 1966: 147–150)

Kandel conceived the study of comparative education to be ‘an interdisciplinary study’ and ‘like the history of education, may, in fact, lay greater emphasis on the ancillary studies than on education’. As such, ‘...so far as methodology is concerned, comparative education may be considered a continuation of the study of the history of education into the present’ (Kandel, 1959: 273). Echoing Michael Sadler, his mentor, Kandel explained further his historical approach:

...the comparative approach demands first an appreciation of the intangible, impalpable, spiritual and cultural forces which underlie an educational system; the factors and forces outside the school matter even more than what goes on inside it. Hence the comparative study of education must be founded on an analysis of the social and political ideals which the school reflects...In order to understand, appreciate, and evaluate the real meaning of the educational system of a nation, it is essential to know something of its history and traditions; of the forces and attitudes governing its social organization, of the political and economic conditions that determine its development (Kandel, 1933: xix).

An Idealistic Philosophical Humanist

As noted above, and as Kazamias and Schwartz had elaborated in an earlier study (Kazamias and Schwartz, 1977), Kandel was an ‘idealist’ intellectual. What we compare, according to him, was more ideals, aims, ideas and ‘forms’. He conceived of

comparative education as a branch of the philosophy of education, and in terms of its methodology and value, as an inquiry into the history of ideas and 'forms'. He wrote:

The chief contribution, then of the study of comparative education is that, if properly approached, it deals 'with fundamental principles' and fosters 'the acquisition of a philosophic attitude' in analyzing and therefore stimulating a clearer understanding of the problems of education. The study makes the education better able to enter the spirit and tradition of the educational systems of his own nation (Kandel, 1955: 12; Kandel, 1933: xx).

It would be important here to clarify Kandel's previously mentioned notion of understanding, appreciating and evaluating 'the real meaning of the educational system of a nation'. As an idealist, he was more concerned with 'form' than with the details that make up an educational system. Beyond the study of the history and traditions, the social, political, cultural and economic 'factors and forces outside the school', or the 'political, economic, and cultural context in which it [the educational system] functioned', Kandel, like Sadler, stressed that the comparative approach demands 'an appreciation of the intangible, impalpable spiritual and cultural forces which underlie an educational system'. And, in contrast to the approach and language of the 'empirical scientists,' Kandel, on occasion, talked about 'hidden meanings', 'real meanings', and 'essence' (Kandel, 1933: xix). Clearly, 'his intellectual orientation was that of contemporary philosophical humanists' (Kazamias & Schwartz, 1977: 156).

A Liberal Democratic Individualist

In a previous study, Kazamias and Schwartz characterised Kandel as a liberal individualist' and a 'passionate devotee of Western democracy' with its basic principles of 'liberty, equality and fraternity'. He saw the contemporary political world in terms of two competing political 'ideals' and 'states,' namely, liberal democracy and the liberal democratic state (as exemplified by England and France, but most of all, by the USA), which he praised, and totalitarianism and the centralised, autocratic and dictatorial state (exemplified by fascist Italy, Nazi Germany, and communist Russia), which he abhorred. In this connection, we also noted that Kandel's liberal ideology 'bore strong similarities to traditional British liberalism with its emphasis on "limited state interference in social policy"'. Clearly, therefore, he would be against welfare statism, social engineering, or social reconstructionism' (Kazamias and Schwartz, 1977: 156–157).

It is pertinent here to comment on the preeminent role Kandel assigned to the political factor, specifically to the 'state' in the operations of society, particularly in education. In his 1933 classic text he stated that CE was a branch of politics, and more pointedly, that 'every state has the type of education that it wills' and 'as is the state so is the school'. He elaborated:

The specialist in comparative education should have a knowledge of varying political theories, especially as they bear on the relations of the state and the individual...[both Plato and Aristotle] early enunciated the principle which was

later expressed in the phrase ‘as is the state, so is the school’ or ‘what you want in the state, you must put in the school’ (Kandel, 1933: 274–75).

This element in his approach differentiates Kandel from the other historical-cultural and liberal humanist comparativists. The political dimension of education has been an *epistemic* concern of most modern comparativists. But Kandel was the first comparativist to use the ‘state’ as a contextual explanatory variable in the comparative study of education. Stripped of the ideological biases and the melioristic preconceptions, noted below, Kandel’s examination of education from the political prism of the state was, in my judgement, an important epistemological and methodological insight. Subsequently, in the 1970s and 1980s, the ‘state’, although interpreted/approached differently from that of Kandel, was brought in as a crucial variable in comparative education studies (Carnoy; Carnoy and Samoff; Dale).

Kandel’s important insight on the role of the state in the comparative study of education was vitiated/marred by at least three weaknesses/flaws: (a) First, his categorisation of contemporary states into two ‘ideal types’, namely ‘totalitarian’ and ‘democratic’; (b) Second, his bias, on the one hand against non-Western polities, especially Soviet socialism, and on the other, in favour of Western ‘liberal democracies’, especially the Anglo-Saxon variety (e.g. UK and USA); and (c) Third, his compounding of the ‘normative’ with the ‘descriptive’ in his conceptualisation of the state; he saw in the actual states (democratic, totalitarian) what he theorised such states ‘ought to be like’, rather than what they were. Kandel never really probed into the actual distribution of power in liberal democracies, a notable omission at a time when it was quite obvious that in advanced liberal industrial capitalist democracies, class differences, conflicts, racism and inequalities were the subject of much socio-political and educational discourse as well as much activism.

A Historical-Philosophical Meliorist

In an earlier study (Kazamias, 1961), I wrote that one important element in Kandel’s historical-philosophical approach ‘may be termed the *melioristic purpose*’. I explained further:

In both his 1933 and 1955 works, Kandel exhibits great concern for the improvement of education in the world. He hoped that by studying other systems as well as his own, the student of comparative education would develop a more desirable philosophical approach that would ultimately result in the improvement of his own system, and in fostering the spirit of internationalism. This purpose has led Kandel to assume a certain body of values, e.g., democratic systems of education are better, centralization is bad, education should aim at the total development of man, and such beliefs as progress, individual responsibility, and so on (Kazamias, 1961: 91).

There were several sources of Kandel’s meliorism. In the first place he agreed with the diagnosis of the need for ‘educational reform and reconstruction’ which many

leaders in all walks of life made during the years following the two major world wars. 'The new social, political and economic conditions and the cultural and intellectual unrest engendered by these', he wrote in 1933, 'gave an added stimulus to the movements for reform in England, Germany and France' which had been gathering strength for several centuries (Kandel, 1933: xvi). In the second place, Kandel saw clearly that the militaristic nationalism and xenophobia of the first quarter of the twentieth century were becoming anachronistic. He hoped that the comparative study of education might lead to the 'development of an internationalism based not on emotion or sentiment, but arising from an appreciative understanding of other nations as well as his own' (Kandel, 1933: xxv). He feared the destructiveness and anti-individualism of 'a dictatorship of personal power and authority or of a dictatorship of an idea' by types of government which he saw spreading in his lifetime. He hoped, through education, to encourage the development of 'cultural nationalism', as opposed to 'political nationalism' (Herzog, 1960). In short, as I stated in an earlier study, Kandel's meliorism was shown by '(a) the belief in certain values concerning how men should live and how they should educate their children; (b) the view that the study of comparative education should be governed by a reforming zeal; and (c) that education, in the Kandelian sense of formal schooling, can indeed improve society and guide man's destiny' (Kazamias, 1963: 385).

Nicholas Hans—the Historical-Humanistic Approach: A 'Factorial Interpretive Framework'

Nicholas Hans, an Eastern European émigré to England, acknowledged his intellectual debt to both Sadler and Kandel (Hans, 1952), but of all the 'forgotten' historical-philosophical and liberal humanist pioneers in comparative education, he was the most systematic in his acknowledged historical approach to the study of educational problems in different countries. Unlike Sadler, Kandel and Robert Ulich, Hans sought to explain and illuminate educational phenomena and systems from the perspective of a specified conceptual framework. As Tretheway has pointed out:

Hans' contribution, therefore, was not in supplying a transatlantic version of Kandel's method, though their work did have much in common. His particular contribution was in developing a framework for comparative study comprised of factors which he believed represented immanent and permanent forces which shaped nations and their educational systems. The value of such framework lay in the order or structure it imposed on a potentially unmanageable quantity of relevant data and, of course, in the usefulness of the studies applying it (Tretheway, 1976: 63–64).

A key concept in Hans' framework is the term 'factor', hence one could describe his approach as 'factorial analysis'. The essence of comparison, according to Hans, is (a) the identification of a set of factors which make up/form/constitute the 'physiognomy' or the 'character' of a nation-state, and (b) the comparative analysis of

the functional relationship between these factors and education or the influence of these factors in the 'creation' of national educational systems. The main purpose of comparative education is the 'analytical study of these factors from a historical perspective and the comparison of the attempted solutions of resultant problems' (Hans, 1949: 10–11).

In his classic text *Comparative education: A study of educational factors and traditions* (1949) Hans explained further:

...national systems of education as well as national constitutions or national literatures are the outward expression of national character and as such represent the nation in distinction from other nations. If we could separate and analyse the factors which historically were active in creating different nations we should get a long way to a definition of the principles which underlie national systems of education (Hans, 1949: 9–11).

The pre-determined key factors in Hans' historical approach were classified in three groups: Group I-Natural factors, e.g. Race, Language, and Environment; Group II-Religious factors, e.g. Catholicism, Anglicanism, and Puritanism; and Group-III Secular factors, e.g. Humanism, Socialism, and Nationalism. To these 'key factors', Hans added: 'To Part II we add an introductory chapter on religious influences in general and to Part III we shall add a concluding chapter on Democracy and Education' (Hans, 1949:16).

An illustrative example of Hans' historical-factorial-functional analysis is his use of 'nationalism', a factor that was also important in Kandel's historical-philosophical approach. First, Hans identifies 'nationalism' as a significant universal 'secular' movement, and in language similar to that of Kandel, as the 'natural expression of national character'. After clarifying the terms 'nationality' and 'nationalism' he refers to the thought of the 'prophets' of nationalism, namely, the German J. G. Fichte and the Italian Giuseppe Mazzini. This is followed by a reference to Slavic nationalism, which in turn, leads to a more detailed description of the 'fascist phenomenon' in the thought of Giovanni Gentile and the policies of Benito Mussolini, and in the Nazism and racism of Hitler's Germany. Paralleling the description and explanation of the 'fascist phenomenon', Hans refers to those aspects of national educational systems which, in his analysis, were related to or were influenced by the nationalist movements. From Hans' historical perspective, the educational system of Italy during the hegemony of Mussolini and Gentile could be illuminated by examining it within the context of Italian fascism, while that of Germany within the context of German national socialism, i.e., Nazism (Hans, 1949: 215–234).

Another example of Hans' factorial analysis, which again reminds us of Kandel, is his comparative analysis of education in different countries from the political-ideological perspective of 'democracy'. Hans avoids Kandel's classification of contemporary politics/political systems into 'democratic' and 'totalitarian', and, unlike Kandel, he does not conceptualise uncritically liberal democracy. He distinguishes between the Anglo-Saxon concept of democracy—represented by England and the USA—with its emphasis on 'political freedom', and the Socialist—represented by the Soviet Union—with its emphasis on social equality. But both types of state/polities are called 'democracies'.

Like Kandel, Hans considers the Soviet state and existing kindred socialist systems as not conforming to the democratic principles of equality and freedom to the same degree as the American and the French states/polities. Nevertheless, neither the political-liberal democracy of England and the United States, which he favours, nor the socialist democracy of the Soviet Union, when taken separately, 'can safeguard the freedom of cultural development and the equality of educational opportunity, which are declared by both to be their goal'. He then elaborates on this theme and concludes: 'From these examples it appears that neither the Anglo-Saxon interpretation of democracy as political freedom nor its Soviet interpretation as social equality have resulted in practice in establishing a true equality of educational opportunity for all citizens of their countries. We cannot escape the conclusion that both interpretations of democracy as practiced at present are defective' (Hans, 1949: 236–237).

To a greater degree than the other forgotten historically-oriented comparativists, Hans envisaged comparative education to be also an 'applied subject'. Unlike comparative anatomy and comparative religion, according to him, 'the purpose of Comparative Education is not only to compare existing systems but to envisage reform best suited to new social and economic conditions ... thus our subject has a dynamic character with a utilitarian purpose'. However, he went on to say that being an applied subject it depends largely 'on conceptions and aims of education supplied by philosophy of education and on the data supplied by the history of education, and by sociology and economics' (Hans, 1952: 57).

Robert Ulich: A Humanist Historian

Unlike Kandel's and Hans', Robert Ulich's approach to the study of education in different nations was more historical than comparative. Its title notwithstanding, his book *The Education of Nations: A comparison in historical perspective* (1961), is really a cultural and intellectual history of the West. In it he first examined the cultural movements (Medievalism, Renaissance and Reformation, Rationalism, Science and Technology), which, according to him, characterised the history of the western world and western culture. He then provided historical accounts of the development of the educational systems of France, England Germany and Russia. In the end, he formulated certain generalizations about educational problems in the 'new nations', through which, he averred, the older nations had gone.

Ulich's historical analysis of the stages of development of western culture/civilization is both scholarly and insightful. But the comparative aspect is truncated. As I have commented shortly after Ulich's book was published: 'The reader must make the comparisons himself based on the assembled historical facts and interpretations' (Kazamias, 1963: 387).

Robert Ulich was German. Though he held high academic and administrative positions in his native land, at the age of 44 he left Nazi Germany and emigrated to the United States rather than compromise his social democratic beliefs with the fascist Nazi regime. Like Sadler, Arnold and Kandel, he was nurtured in the Eurocentric classical humanistic intellectual and cultural tradition, and as a university professor and

researcher in America, he attained national and international reputation as a scholar, an educational philosopher, a cultural historian and a comparativist.

In an 'In Memoriam' note on Ulich, titled 'A humanistic gift from Europe', shortly after his death in 1977, Paul Nash, one of his students and friends at Harvard, characterised Ulich's 'contribution to comparative education' as quintessentially 'humanistic' (Nash, 1977: 147). In Nash's assessment, there were four 'dimensions' to Ulich's humanistic approach. First, there was Ulich's 'determination to keep the human being firmly at the center of the educational picture; for Ulich, the person was always central, rather than the curriculum, the discipline, the field, the institution, or the research'. Second, Ulich's approach was 'unapologetically and thoroughly historical; he believed that it is impossible to comprehend the nature of the educational process without understanding its historical context'. The third dimension of Ulich's humanistic approach, according to Nash, 'lay in the human relevance he saw in comparative education for the education of teachers'. In this respect, Nash added: 'He [Ulich] viewed without enthusiasm the development of comparative education as a recondite activity for scholars and researchers who produce analyses, graphs, tables, and theories that are of interest only to one another (and sometimes only to themselves)'. Lastly, in Nash's assessment, 'Ulich's humanistic approach was marked by a strongly political value system ... he was a lifelong social democrat' (Nash, 1977: 148–149).

As a postscript to this intellectual profile of Robert Ulich, I should like to add a personal note. I too was Ulich's student at Harvard at the same time as Nash, who was a close friend. With Henry Perkinson, another of Ulich's students and a friend, Nash and I co-edited a book entitled *The Educated Man: Studies in the History of Educational Thought* (1966), which was dedicated to: 'Robert Ulich' with the appropriate added appellation 'An Educated Man' (Nash *et al.*, 1965). Ulich was indeed a classical humanistic scholar in the best sense of the German tradition that also included, among others, Werner Jaeger, his contemporary, who wrote the three-volume classic *Paideia: The Ideals of Greek Culture* (Jaeger, 1939/1939). Robert Ulich was also an inspiring teacher. Strictly speaking, he was not a 'comparativist' but a humanistic historian and a philosopher, but he inspired some of his students, specifically George Bereday and myself, to become historically-minded comparativists.

Forgotten Men, Forgotten Themes: A Reassessment

In the 1960s, comparative education as a cognitive *episteme* went through a major identity crisis. Partly as a consequence of political, economic and intellectual developments, namely, (a) the emergence of 'new states' bent on building both viable polities/nation-states and viable economies, (b) the emphasis on re-constructing the 'old nations' along more welfare-state democratic principles, and (c) the dramatic developments in technology, the natural sciences and the empirical social sciences, education as a political, economic and socio-cultural mechanism was given top priority in the re-shaping and re-construction of the new political, economic and socio-cultural *cosmos*. The new political, economic and intellectual climate had a determining influence on the epistemological, methodological and ideological orientations of the new

generation of comparative educationists, particularly in the United Kingdom and the United States.

During this period a new generation of comparative educationists and a new generation of comparative education discourse emerged in the United Kingdom and North America. At the same time, there was a regeneration of comparative education as an academic field of study with practical and melioristic extensions; a professional society—the US-based Comparative Education Society, later the Comparative and International Education Society—was organised; and a scholarly journal—*The Comparative Education Review*—was launched in the United States. In this contextual milieu, the new player-comparativists, many of whom were educated in more modernist *epistemic* approaches and traditions, searched for new intellectual frameworks and methodological approaches in their study of foreign systems of education and in making ‘inter-national’ comparisons.

In such a political and intellectual atmosphere, the value of the historical-philosophical-cultural and liberal humanist generation of comparative discourse, examined above, was discussed and judged to have noteworthy limitations. If the inspirational deities of the old player-comparativists were history, philosophy and ‘humanistic culture/*paideia*’, those of some influential modernist ‘scientific’ parvenus were ‘science’ and the ‘scientific method’, ‘empiricism’, ‘instrumentalism’ and ‘technocratic rationalism’.

In the many texts on the nature and scope of comparative education that appeared in this transformative period of the 1960’s, the critical comments and observations about the historical-philosophical humanist comparativists discussed in this chapter were of the following kind:

- (a) They [‘the historian comparative educationists’ to Holmes’ characterisation] were ‘humanists’ not ‘scientists’, insightful but ‘qualitative’ not ‘quantitative’, subjective not objective. Commenting on the ‘historical approach’ as used by comparativists, the scientifically-oriented methodologists Noah and Eckstein, in their often-cited text *Toward a Science of Comparative Education* (1969), noted critically that ‘their conclusions rely largely on the private insights of their authors, not only regarding which categories are valid and which data are relevant, but also on the matter of what quantity and quality of evidence constitute proof of a particular assertion’ (Noah & Eckstein, 1969: 188). In their historical account of the development of the field, Noah and Eckstein placed such historically-oriented comparativists as Kandel and Hans in the ‘pre-scientific’, so-called ‘forces and factors’ phase of the field’s evolution. Kandel’s approach, according to them, ‘provided no way of judging their [the factors’] importance relative to each other.... Nor was there apparent any criterion for the inclusion of some factors in the analysis and the exclusion of others, except on the basis of “self-evident truth”’. And further: ‘What appeared in Kandel’s work s persuasive conclusion are in fact important hypotheses remaining open for testing’ (Noah & Eckstein, 1969: 51).

In England, Brian Holmes, a contemporary exponent of the ‘scientific approach’ to the comparative study of educational problems, also assessed

‘historical comparative education’ as being no substitute for ‘scientific comparative education’ whose hallmark was ‘prediction’ rather than ‘explanation’. Comparative education, according to Holmes, must be a ‘generalising science’ and comparative educationists must be ‘social scientists’. And in the same text: ‘invaluable as historical research and related analyses are, educational reformers are primarily interested in the consequences of their actions, not in the causes of their present dissatisfaction’; and, rather gratuitously, he added that history could be of pragmatic value in ‘illuminating present problems’ or it ‘can ... contribute to that practical knowledge which gives directive or predictive power—namely, science’ (Holmes, 1965: 19–21).

- (b) Some were ‘historicists’, in Karl Popper’s meaning of the term (Popper, 1961) in that they searched for or espoused absolute, final and inexorable laws of development; others that were ‘historicists’ in C. A. Anderson’s and Philip Foster’s meaning of the term (Anderson; 1961; Foster, 1960) in that they did not generalise or they dealt with particular events that were temporally and spatially located and, therefore, quite unique.
- (c) They were mainly concerned with ‘explanation’ and ‘understanding’ not with ‘prediction’ or ‘reform; as such, they were ‘backward’ not ‘forward’ looking; they searched for ‘antecedent causes’ for ‘forces and factors’. As Noah and Eckstein asserted: ‘They (e.g. Kandel, Hans and the other “historian comparativists” were primarily intellectuals intent on explanation, rather than activists in the field of educational policy-making’ (Noah & Eckstein, 1969: 57). And, in a similar critique, ‘understanding’, according to Holmes, ‘comes through successful prediction rather than through the discovery of antecedent causes’ (Holmes, 1965: 30).
- (d) In 1970, commenting critically on Sadler’s historical approach, one however that was also espoused by Kandel, E. Epstein wrote: ‘The Sadlerian emphasis on intangible, impalpable, spiritual forces borders on mysticism and in its extreme leads to unwarranted conclusions about the nature of education’. He added: ‘The premise that comparative education is basically a humanistic activity—because the fundamental explanatory concepts that pertain to schools refer to unempirical forces—is a call for scholars to describe the external manifestations of the structures of school systems, and to speculate loosely on the rest or leave it to spiritual revelation’ (Epstein, 1970: 45).

It would be quite in order here to point out that as a member of the postwar new generation of students of comparative education, who were actively engaged in the redefinition and reconstruction of the field, I was one of the first comparativists who commented critically on Kandel as a historian and a comparativist, as well as on Kandel’s methodology and his intellectual/epistemic orientation. At the same time, I made some general critical remarks on the historical approach of the other historical comparative educationists. In 1961, commenting specifically on Kandel I wrote that Kandel’s methodology was governed by at least three major purposes: the *reportorial-descriptive*, the *historical-functional*, and the *melioristic*. Referring specifically on Kandel’s historical approach, I criticised his tendency to blend the descriptive, interpretative and explanatory elements

of his historical analysis with the melioristic, the ‘what is’ with the ‘what ought to be’. ‘The historian’s task’, I explained, ‘should be to describe and illuminate certain phenomena, not to prescribe’ and added: ‘Any historical treatment that is governed by considerations for improvement tends to lead to what Herbert Butterfield called ‘Whiggism’...In short, the historian should view phenomena in their contemporary context regardless of whether this might lead to future improvement of practices or ideas’ (Kazamias, 1961: 90–91).

Another element in Kandel’s historical approach, and, I might add, in the approach of other contemporary historically-oriented comparativists (e.g. Sadler, Hans, and Vernon Mallinson) that I criticised, was his propensity to theorise about society and to explain the nature of educational systems in terms of the concept ‘national character’. In the same text, I pointed out that Kandel’s observation that ‘English education is characterized by lack of system’ (Kandel, 1933: 94) could be explained by the alleged national English psychological character trait that ‘the Englishman dislikes to think or formulate plans of action’ (24–25), could not be considered as a creditable historical interpretation that was based on historical or other kind of creditable evidence. Moreover, as Joseph Lauwerys, whom I quoted, pointed out ‘in the end “national character” could be made to explain anything and everything’ (Lauwerys, 1959: 285–287). Another example of Kandel’s use of ‘national character’ to explain differences in national systems of education, that can be questioned, was the following:

If the Englishman is a man of action whose progress is marked by empiricism rather than by theory, the Frenchman is a man of ideas who enjoys to think for the sheer pleasure of thinking and generally without much concern for the outcome of thinking in action. Orderliness, logic, planning, which appear to be absent as the characteristics of English life and organization, are by contrast the outstanding features of the French (Kandel, 1933).

In commenting on Kandel’s approach to comparative education—his comparative methodology—I was quick to make the additional point that my criticisms referred specifically to certain elements in Kandel’s version/variety of history. Such elements included, *inter alia*: his meliorism, his political and educational ideological predilections and biases, the Olympian scope in his examination of national systems of education, his use of the rather nebulous social-psychological concept of ‘national character, and the predominant role he assigned to the state in his ‘historical functional analysis’. However, I also entered the important caveat that my criticisms were not aimed at the historical method as such in the comparative study of education. I stressed then and elaborated in subsequent statements on the same theme, that ‘history has a valuable place in comparative education’. At the same time, I criticised those contemporary comparativists, e.g. Noah and Eckstein and Brian Holmes who saw little value, if any, in historical comparative education in that it was not a ‘science’ or a ‘generalizing science’. I also commented on Philip Foster’s and C. Arnold Anderson’s critical observation that in so far as history essentially dealt with unique phenomena with an ineradicable temporal and spatial locus, its value for comparative education was at best limited. Since comparisons could not be made of unique events or phenomena, Foster and Anderson had argued, the comparative educator’s task differed from that of the

historian and became identical to that of the ‘social scientist’ who searched for repetitive patterns and regularities in social relationships (Foster, 1960; Anderson, 1961).

In my comments on the ‘unscientific’ nature of history and the other criticisms leveled against the historically-oriented comparative educators I sought to clarify certain misconceptions and counter some of the criticisms made by the 1960 new generation of ‘scientifically-oriented’ comparativists. I pointed out that the criticism that historical comparative education was ‘unscientific’ was itself based on the restrictive interpretation of the English term ‘science’, which, more often than not, refers to the epistemology and methodology of the natural sciences or the empirical positivistic social sciences. But, I argued, the word ‘science’ might also refer, as indeed it does in other languages, to the ‘human sciences’ or to the systematic study of social, cultural and human phenomena, the strategies of knowing or the knowledge derived therefrom. The German term *Wissenschaft* and the Greek word *episteme* denote intellectual systems that apply to both the arts and the sciences. If ‘science’ is interpreted in the broader sense of *episteme* or *Wissenschaft*, then Sadler’s, Kandel’s, Hans’ and Ulich’s versions of historical comparative education could legitimately be called ‘scientific’. Indeed, as quoted above, Hans’ characterised comparative education, which of course included his own historical version, as *Vergleichende Erziehungswissenschaft*, and further, as an academic discipline that ‘[it] is just on the border line between humanities and sciences and thus resembles philosophy, which is the formulation of both’ (Hans, 1959: 299).

Turning to the assertion made by Foster and Anderson that history deals with unique phenomena that are temporally and spatially located and consequently its value for comparative analysis which presupposes abstraction, generalisation and regularity is questionable, I argued that such a claim has been refuted by several writers, including historians. In 1963, I wrote:

As Crane Brinton [the eminent comparative historian] has shown, it is quite possible to categorize or classify historical phenomena and compare them for the purpose of making generalizations. Although such generalizations may be of a limited rather than a universal nature, they may in turn be used as working hypotheses to be tested in other similar situations in order to illuminate them. In other words, from an examination of the specific, the concrete and the particular, the historically-minded comparative educator may induce a generalization and then use it in order to illuminate another particular event or form.

And I added: ‘The concern for the general and the particular is to be found in both the social sciences and in history, and the difference is one of emphasis and objectives of research rather than kind and method’ (Kazamias, 1963: 396).

In a reassessment of the historical-philosophical-humanist discourse in comparative education, I wish to emphasise that Sadler, Kandel, Hans, and Ulich, four of its most noted exponents, approached education not just from the narrow sense of ‘schooling’ but from the broader sense of *paideia/culture*, and comparative education as a ‘humanistic *episteme*’ whose major concern should be with the ‘human being’, the *anthropos* (‘man’). As such, it should therefore be *anthropocentric* (‘man-centred’); it should

be pervaded by a ‘humanistic’ philosophy, and it should be concerned with the great problems—political, social but also ethical—which ‘mankind’ faces.

THE SCIENTIFIC PARADIGM IN COMPARATIVE EDUCATION

Dimitris Mattheou

The Changing Educational Context and the Quest for a New Paradigm in Comparative Education

Comparative Education as an academic field of study was born in the aftermath of the establishment of state systems of education; in an era when the humanities dominated the school curriculum in Europe, when *Bildung* in Germany, *Culture Générale* in France, Liberal Education in England or *Klassiki Paedeia* in Greece had basically the same ultimate aim; the preparation of intellectually, morally and aesthetically cultivated individuals, allegedly capable and willing to provide good service to their country and to mankind.

Natural sciences, which had only recently (by the second half of the nineteenth century) managed to find a place in the curriculum, were still struggling to prove themselves in terms of their contribution to the development of human faculties, such as discipline, accurate observation, critical analysis, etc. (McLean, 1995; Lawton, 1976; Whitfield, 1971; Mattheou, 2006). Science as a form of knowledge had undoubtedly won a name for itself (Davies, 1997: 790–794); its achievements could hardly be overlooked. On the contrary, there was a ‘general conviction that scientific methods could and should be applied to the study of human as well as natural phenomena’ (Davies, 1997: 794).

And it was in this intellectual climate that Comte, one of the fathers of modern sociology, introduced scientific positivism in the study of society. Yet, despite these developments and the thorough criticism of people like Herbert Spencer, many intellectuals, educators, educational authorities and members of the leisure class remained firm in their point of view; for all its weaknesses, drawbacks and failures humanistic education embedded in the classics continued, to their way of thinking, to constitute the cornerstone of education, the complete system of timeless values and eternal verities (cf. the views of the 1864 Clarendon Commission in England, Matthew Arnold, 1869, Wilhelm von Humboldt, 1961, etc.).

This humanistic spirit prevailing in education at that time had certainly exerted an influence on the nascent cognitive domain of Comparative Education. The founding fathers of the field, among them M. Sadler, I. Kandel and later on N. Hans and R. Ulich, approached the study of foreign systems of education with a melioristic, holistic and idealistic outlook (Kazamias & Schwartz, 1977; Noah & Eckstein, 1969).

Convinced that ideas and ideals fundamentally influence men's actions, they looked for 'the intangible, impalpable spiritual and cultural forces which underlie an educational system' (Kandel, 1955: xix) and which, therefore, potentially contribute to the betterment of society. As genuine humanists they turned to history and to philosophy for help. Moreover, the international circumstances during the first half of the twentieth century, especially during the mid-war years, favoured this attempt: 'at a time when economic depression, rising nationalism, the emergence of modern authoritarian ideologies [threatened peace]... the problems of the democracies preempted the attention of educators all over the world' (Noah & Eckstein, 1969: 50) and consequently shaped the priorities of comparative educators. They looked into the 'forgotten struggles and difficulties' of the past and into 'battles long ago' (Sadler, 1964), into the educative influence of religious and secular factors – democracy, humanism, nationalism and socialism (Hans, 1958) – in an attempt to understand the dynamics of educational development that would in turn allow policy makers, if they so wished, to improve human condition.

By the end of the Second World War, circumstances had changed. Faith in humanistic studies had diminished: not only had educated elites failed to prevent atrocities, but on several occasions they had played a leading role in the abhorrent war drama: 'militarism, fascism, and communism found their adherents not only in the manipulated masses of the most afflicted nations but amongst Europe's most educated elites and its most democratic countries' (Davies, 1997: 899). The post-war 'Dark Continent' was in search of 'blue-prints for the golden age' (Mazower, 1998: 185). Education for economic development and democratisation – presumably a key element for individual and social improvement – became a central theme of the educational discourse of the time (Adams & Farrell, 1967; Sobel, 1982). Policy making and successful reform had consequently come to the forefront, and both politicians and academics were trying to find ways to respond to the new demands.

In comparative education, a new generation of comparativists felt increasingly unhappy with the historical approach. They maintained that the prevailing historical approach was too macroscopic in its perspective, too ambitious in its orientation, too qualitative in its approach, heavily melioristic and in any case irrelevant to the pressing needs of education which at the time had to cope with the problems posed by the pursuit of reform (Noah & Eckstein, 1969.; Kazamias, 1961; Mattheou, 1997; Holmes, 1965). The climate for a change of paradigm in the field was thus quite favourable.

Impressive developments in the natural and the social sciences were already pointing to a most promising paradigmatic alternative. Actually, the 'growing respect for science ... affected all branches of study. The social sciences [in particular]... exerted a profound effect on all the older disciplines' (Davies, 1997: 1076). For instance, in sociology and economics the refinement of measurement techniques and of the statistical processing of data had generated great hopes that objectivity in the study of social phenomena could be achieved and that the laws governing their course could be expressed in a mathematical form (Kerlinger, 1965; Cohen & Nagel, 1934). For many comparativists the strengths of the scientific method, its explanatory and prognostic power, its accurate observational techniques, its systematic and thorough empirical

testing of hypotheses, its precise measurements, and its probing and fact-finding approach could hardly be ignored (Noah & Eckstein, 1969; Anderson, 1961; Holmes, 1965). Equally confident and optimistic for the strengths of the scientific method, a host of technocrats, technical advisors, bureaucrats and politicians were involved in the scientific planning of reform, believing that this was the only safe means to overcome socio-economic difficulties (cf. the work of the International Institute for Educational Planning).

The Scientific Paradigm: The Question of Aims and Laws

In this context of optimism and wishful thinking it is not strange that by the late 1950s comparative education was in search of a new 'scientific' identity. A fundamental prerequisite for the field to acquire scientific status was, according to the critics, the abolition of impressionism, subjectivity, speculation, intuition and predisposition, generically linked, with its qualitative and value-laden character, as this had been nurtured by the historical and philosophical work of its forefathers (Templeton, 1958; Epperson & Schmuck, 1963; Clayton, 1972). Yet, transformation was far from easy. Firstly, established schools of thought or paradigms, according to Kuhn (1970:7), never die out silently and voluntarily, as their exponents are ready to defend them. Secondly, consensus as to what actually constitutes science was far from being unanimous, especially in terms of the study of society. Hence, comparative education literature during the late 1950s and mainly during the 1960s was intensely occupied with questions of aims, content, theory and practice and most significantly of methodology in comparative education.

One way to follow these debates is to make use of a classificatory system based on the elements that constitute the Kuhnian paradigm, namely goals and subject matter, theory and exemplary practice, research rules and standards, application and instrumentation (Kuhn, 1970: 10 ff).

In what follows the discussion focuses on the question of 'aims and laws' – the latter being also an essential part of the 'subject matter' and by the same token closely linked with 'theory' – and on 'epistemological and methodological issues' pervading both 'research rules and standards' and 'application and instrumentation'.

A significant paradigmatic shift concerned the aims of Comparative Education. In the new paradigm the field retained its ambitious aim to understand and to explain the workings of education and its relationship with the broader social context. Yet understanding and explanation should not be based any longer on the intuitive, cultivated and sensitive mind of the comparativist but on a hard-core scientific theory, comprising laws and verifiable quantitative hypotheses that would stand exhaustive empirical test.

The position of Bereday, who served as a bridge between the historical and the scientific paradigm, is characteristic in this respect. While his first three steps aimed basically at understanding and explaining specific educational phenomena, his ultimate aim remained total analysis; an exercise, i.e. which 'deals with the imminent general forces upon which all systems are built' and which lead to 'the formulation of 'laws' or

'typologies' that permit an international understanding and a definition of the complex interrelation between the schools and the people they serve' (Bereday, 1964: 23–25). Establishing laws, as the mature sciences did and as some social sciences – especially economics – aspired to do with significant probability of success, became a dominant methodological discourse for comparative education.

Agreement on the necessity of formulating laws did not however imply consensus as to the character of these laws. C. A. Anderson, as a sociologist, for example, would speak of 'patterns comprising abstracted social systems, exploring relationships of essentially undated and often timeless nature' (Anderson, 1961: 4), while in the same vein Foster would refer to the invariant relationships that exist 'between educational institutions and the institutional matrix in which they function' (Foster, 1960: 116). Although 'the perennial difficulties of sifting out generalities from the maze of institutional particularities' were recognized, C. A. Anderson – echoing the optimism and perhaps an element of positivism inherent in functionalism, a dominant theory in sociology at the time – appeared to be certain that the 'continued pursuit of comparative education' in this direction 'has great promise' (Anderson, 1977: 415–416). Clearly, his confidence as to the scope and purpose of comparative education was based on the assumption that such timeless and universal generalisations do exist and can be revealed through sociological research, provided that proper use of ever-improving research methods and techniques would be made.

On their part, Harold Noah and Max Eckstein seemed also confident that the ultimate aim of comparative education is to provide well-tested and refined generalisations. These generalisations were seen as 'functional relationship(s) between dependent and independent variables' expressed in propositions that preferably take the mathematical form of 'as x changes so y changes' (Noah & Eckstein, 1969: 93). Like structural functionalists, they too looked for universally valid explanations of how things are and how they actually function instead of searching for antecedent causes. Being aware however of the difficulties of such a project and of the pitfalls inherent in covariational relationships they were at pains to underline that 'a statement of a functional relationship ... need not necessarily refer to causal relationships', that 'it may not reveal the direction of influence from one factor to another' and that '...the precise mechanism by which x causes y may still remain unstated' (Noah & Eckstein, 1969: 96). They stressed the need for an unceasing refinement of explanatory propositions, every time that comparative evidence would divulge that these propositions constitute an ad hoc and a 'simplistic explanation of the phenomena' under consideration (Noah & Eckstein, 1969: 120). Finally, all these elucidations may explain why they did not give the status of 'laws' to their universal explanatory propositions.

This was not the case for Brian Holmes, another prominent adherent of the scientific approach in comparative education. Trained originally as a physicist he was imbued with the notion that the world, physical as well as social, is governed by laws; that 'God does not play dice', as Einstein had once said. Consequently, the student of comparative education had to start his work by appreciating the existence of laws governing the educational world.

Following the Popperian critical dualism, Holmes drew however a distinction between normative and sociological laws; 'between the man-enforced normative laws or

conventions and the natural regularities which are beyond his power'. Normative laws 'are man-made and can be accepted, rejected or changed by man' (Holmes, 1981: 77), he argues. 'Representing man's beliefs, [they] are part of the context in which schools are run', and hence 'they must be known if we hope to understand how schools function'. Accordingly, 'the establishment of ... normative laws for particular nations represents ... one of the most important of the many tasks a comparative educationist should tackle' (Holmes, 1981: 78). On the other hand, sociological laws, like the laws of physics, 'are man-made statements', that 'apply to the functioning of societal institutions' both inside the school system and outside it (Holmes, 1981: 80). They are 'hypothetical, and if they are to be scientific, [they] should be refutable'. Finally, 'sociological laws are not universally valid: they are contingent', in the sense that, although they constitute 'universal or general statement(s)' they are dependent on 'the conditions under which [they are] to be applied' (Holmes, 1981: 78).

Clearly the Holmesian perception of laws that govern education differ in many respects from those of his American colleagues (e.g. C. A. Anderson and Noah and Eckstein). In the first place, his laws are diversified into two distinct types which actually codify and bring together two different intellectual traditions or schools of thought: the anthropocentric, expressed through man's freedom of the will that pervade normative laws, and the structural functional, inherent in the sociological laws. Second, sociological laws are contingent and hence they are neither a-historical nor unconditionally valid. Prevailing traditions, circumstances and conditions determine the validity and the application of these laws. The influence of relativity theory in physics is obvious in Holmes' perception of sociological laws and overtly stated.

The contingency of sociological laws indicates, among other things, that the aim of scientific comparative education is not the ultimate formulation of either a grand educational theory based on thoroughly tested hypotheses or of absolute and unconditional laws; in this sense, contingency might even pose the question of comparability among substantially different social and educational contexts.

The role Holmes reserves for comparative education is less ambitious. To his way of thinking, comparative education should focus on the study of a specific educational problem with the aim to analyse it in context, to understand and to explain it. Through contextual analysis the 'pure' comparative educationist is expected to formulate refutable hypotheses (i.e. 'hypotheses on which planned reform in education rests' (Holmes, 1981: 78)), extrapolate from them all rationally anticipated consequences or, in other words, proceed to probable predictions as to what the outcomes of policy implementation are likely to be. To the extent that predictions are verified, the problem has been solved/explained, the hypothesis has been tested and has provisionally acquired the status of sociological law. Impressed by the striking success of relativity theory to predict phenomena that had only much later been empirically established (and explained), Holmes inaugurates prediction as the demarcation criterion of science, thus opening up a debate on the method of science in comparative education.

Irrespective of their differences concerning the aim of comparative education as an academic field of study, all three versions of the 'scientific schools of thought' tend to agree on the pragmatic dimensions of the field, on its potential to provide sound advice to policy makers. 'As "pure" scientists', Holmes argues, 'we should attempt to

formulate alternative policies to carefully analysed problems and eliminate those we think will be less successful in particular countries. As ‘applied’ scientists we should be prepared to see how far we can help those responsible for policy to implement adopted policies...’ (Holmes, 1981: 54). After all, hypotheses/sociological laws are, to Holmes’ way of thinking, identical with education policies.

‘Although explanation is’, for Noah and Eckstein, ‘the ultimate goal of all scientific (and hence comparative) work in education’, they also readily appreciate the practical contribution of the field; the help ‘provided to planners trying to improve the effectiveness of educational system’ (Noah & Eckstein, 1969: 187). And of course, many comparativists’ involvement in several technical assistance programmes for Third World countries (e.g. World Bank Projects, AID Programmes) or in national policy-making committees testify to the truth of their intention to treat comparative education as a policy-oriented field of study. This renewed emphasis on policy making on the part of scientific comparative education, which clearly runs against the humanitarian tradition of the founding fathers’ ambition to appreciate ‘the intangible, impalpable spiritual and cultural forces which underlie an educational system’ (Kandel, 1955: xix) and to grasp ‘the hidden meaning’ or the ‘real meaning’, or the ‘essence’ of things, certainly reflects the developmental priorities of the time, both economic and social. This emphasis also reflects faith on the part of political authorities in the effectiveness of rational central planning (cf. 5-year plans, in vogue during the 1950s and 1960s in many countries) which in turn was encouraged by economists’ and other social scientists’ reassurances that science (basically social sciences) was by then in a position to guarantee with a substantial measure of probability the success of the planned, i.e. of the desired predicted outcomes of educational policies (cf. Parnes, 1962; Harbison & Myers, 1964).

Epistemological and Methodological Issues

It would not be unreasonable to infer that optimism was to a large extent based on the impressive record of success in physical sciences (atomic fission and fusion, transistors, etc.) during the war and after it, and of the remarkable advances in social and behavioural sciences as well. As a matter of fact success stories or ‘finished scientific achievements as they are recorded in the classics ... from which each new scientific generation learns to practice its trade’ (Kuhn, 1970: 1) have always contributed to the development of an ‘image of science [which is] persuasive and pedagogic’ (Kuhn, 1970: 1) in the sense that it usually evokes the quest for a ‘more esoteric type of research’ which in turn constitutes ‘a sign of maturity in the development of any given scientific field’ (Kuhn, 1970: 11). By mid-1950s comparative education seemed to have reached this stage. Bereday was among the first to realize it. He insisted that ‘the discussion of methods of comparative education is perhaps the most urgent task which those who research and teach comparative education must face’ (Bereday, 1957: 13). Without rejecting the historical-philosophical approach altogether, he subscribed to the circumspect use of the scientific method. He retained ‘a basic concern with the concepts and data of the social sciences, especially sociology and political science’

(Noah & Eckstein, 1969: 65). Other comparativists too, like Kazamias, agreed that 'comparative education needs to be infected with a more rigorous scientific method' (Kazamias, 1961: 96).

Although unanimous in criticising the traditional historical approach, the new generation of comparativists retained substantially different views on fundamental epistemological and methodological issues.

Each provided a different answer to questions like 'what is science'; 'should comparative education develop its own characteristic methodology or should it borrow from other sciences, and if so, which science should serve as the prototype'; 'is the method of science inductive or deductive'; 'should it be strictly empirical and quantitative or could it be more theoretical and qualitative'; 'what should be the role reserved for history'?

Most would agree that comparative education was by definition an interdisciplinary field, at least in the sense that its interests were overlapping with those of almost all other social sciences, and was hence dependant on their methodologies – comparativists were actually 'shameless borrowers' of other social scientists' approaches (Farrell, 1979). Some, like Edmund King, would even argue that comparative education was itself a method of 'getting at "the truth" of a situation' (King, 1976: 18) rather than an independent field of study.

Yet, each had his own preferences. According to Bereday, comparative education was an interdisciplinary area of study centered around a geographical perspective of education: 'Its specific task', he argued, 'is to bring several of the concerns of the humanities and the social sciences together in application to a geographical perspective of education' (Bereday, 1964: x). On their part, C. A. Anderson and Philip Foster of the University of Chicago Comparative Education Center envisaged comparative education essentially as a branch of sociology. Holmes' preferences lay basically with the physical sciences whose elaborate and efficient methodology he tried to transfer to comparative education by adopting critical dualism which, to his mind, constituted a productive analytical framework for the study of collective human behaviour and of law-like regularities related to the functioning of social institutions.

Preferences of comparativists for certain scientific fields were influenced by their training and occupation as well as by prevailing trends in their academic field of expertise and led to the adoption of different methodological approaches. Bereday had studied at the London School of Economics, Anderson was a sociologist, Foster, a social anthropologist, had studied in the London School of Economics as well as in Chicago under Anderson, Holmes was a physicist and Noah was an economist. As sociologists working in the United States in the 1950s Anderson and Foster followed for the most part the prevailing orthodoxy of structural-functionalism. They investigated both intra-educational and educational-societal relationships, 'of essentially undated and often timeless nature', by isolating and controlling variables, carefully collecting relevant data, empirically testing hypotheses of a covariational character, giving emphasis to measurement and quantitative techniques in an attempt to objectify research, by eliminating the subjective views, beliefs and prejudices of the observer. Noah and Eckstein too appeared to be confident that post-war developments in social sciences, 'the rise of quantitative empirical research', 'the greater availability of

numerical data, an improved technology for storing, manipulating and retrieving data, and the widespread use of new statistical techniques' (Noah & Eckstein, 1969: 58), had improved the scientific character of the social science approach in 'dealing with problems of bias, tendentiousness and even caprice and willfulness' (Noah & Eckstein, 1969: 90); hence their call for the accession of comparative education into the realm of social sciences, especially as it concerns the adoption of 'empirical and quantitative methods of inquiry' (Noah & Eckstein, 1969: 113).

Criticism of this unilateral perception of the scientific method with all its undue emphasis on co-relational, empirical, quantitative and objective character came from many quarters. Kazamias for example, who had advocated a synthesis of history and social science, would not accept as scientific and explanatory covariational studies that failed to make their theoretical basis explicit (Kazamias, 1963; Kazamias & Schwartz, 1970). Other critics like Toulmin (1961) and Barber (1972) would not accept that there was a single method of science utilised by working scientists and that this method provided a guarantee for objective knowledge, which, on top of that, could be universally valid. Interestingly, criticism of this mode of science came also from proponents of the scientific method in comparative education.

Brian Holmes too was not ready to accept that co-relational studies, no matter how skillfully carried out, could ever lead to general propositions of universal validity and he was therefore not ready to accept that these propositions could serve as a reliable basis for valid predictions and trustworthy policy proposals. His first reservation came from the hypothetico-inductive character of the empiricist approach. Carefully collected data on the basis of an intuitively formulated hypothesis – normally involving preconception and bias – could at best lead to its verification only within its frame of reference; this was, according to him, a limitation inherent in the inductive method, which parenthetically was not anymore accepted as the method of (physical) science. His second reservation came from the recognition of the fact that in empirical studies 'too little attention is usually paid to conceptual analysis prior to operationalising variables', as it is assumed that 'unambiguous and meaningful indicators can be identified and operationalised' (Holmes, 1981: 68) without due consideration of the different meanings, different ideologies and value systems they endow concepts with. Finally, according to Holmes, emphasis on empirical testing and measurement, on variables that can easily be quantified, leaves no room for an account of important national or cultural peculiarities; of the Sadlerian 'living spirit' or of the ideological whims of policy makers that have on so many occasions played a central role in decision taking.

To address the limitations of the empirical approach Holmes proposes a different comparative method. He starts by limiting the scope of his investigation. He refuses to get involved in the unfeasible task of discovering universal laws, but prefers to deal with the analysis and resolution of a specific problem, preferably of a 'technical' problem, which exists under certain characteristic and identifiable circumstances and which is of significance to policy making. His immediate reaction, in his problem-solving approach, is to proceed – after the careful analysis of the problem and the appreciation of the 'initial' conditions (the context within which the problem exists and its policy solution will be implemented) have been completed – to the formulation of a hypothesis/policy proposal that would best solve the problem. This proposal

is only tentative, problem-specific and context-specific, refutable and open to testing only through comparing anticipated results, logically deduced from it, with the actual outcomes from its implementation. Holmes' attempt to apply to comparative education the hypothetico-deductive method which, according to him, is the method of physical science is plainly clear. His conviction on the issue and on the plausibility of transferring and incorporating it to comparative education led him to the extensive exploration of relevant epistemological and methodological issues and to the utilisation of various theoretical perspectives from scholars such as Popper, Dewey, Weber, Myrdal, etc.

From all his theoretical stances, prediction as the demarcation criterion of science attracted perhaps the most severe criticism. He was reminded that prediction in human and social affairs is an unfeasible task, given the complexity and uncertainty of society and man's freedom of the will (King, 1967); a criticism to which he responded that prediction is not equivalent to long-term prophecies and in any case it is not about extracting certainties but rather probabilities, a situation that has not prevented people from organising systems of public transportation or from calculating insurance premiums (Holmes, 1981: 79). The heat of the debate had actually inflated the issue of prediction out of its normal proportions.

On the other hand, reflecting perhaps the influence of the English (and European) humanistic tradition in comparative education, the problem-solving approach reserved a place for history (Mattheou, 1993). The use of 'normative patterns' at the cross-national level – this highly internalised set of values and norms inherited from the past, codified in ideal-typical models based on the work of historically renowned thinkers (e.g. Plato, Dewey, Marx) and responsible for human behaviour – is indicative in this respect. The same is true for the 'pattern of mental states' at the national level; those 'lower valuations' or 'mores' which 'constitute, if you will, Sadler's "living spirit", or Mallinson's "national character"' (Holmes, 1981: 83). Thus, in a way, the Holmesian scientific approach came, in my judgement, closer to satisfying Kazamias appeal for a synthesis of history and social science (Kazamias, 1963; Kazamias & Schwartz, 1977).

The eclecticism of the problem-solving approach in comparative education prevented its use in actual comparative research. On the other hand, research financiers and policy makers are sceptical of methodological approaches that do not lead to clear-cut proposals, that are not supportive to ideologically preconceived policies and that do not provide reassurances for their success within their own term of office. So, the scientific method that finally prevailed was that of the American functionalist and empirical school of thought in the social sciences. Major comparative research projects like the IEA studies, followed the empirical-quantitative road.

On the other hand, the scientific methodology that finally prevailed seemed to be compatible with and well-suited to the needs and priorities of educational policy at the time. To some extent one could argue that comparative research of economists and human capital theorists interested in Third World development played a substantial part in laying down the political agenda for education policy making and certainly in providing arguments to educational reformers. Exponents of development education (Harbison & Myers, 1964; Adams, 1977; Anderson & Bowman, 1965) and modernisation theorists (like Wiener, 1966; Levy, 1966) with all their reassuring evidence were the cornerstone of reform almost everywhere, with policy makers prompt to call

upon the hard facts of scientific research. In this sense social science had become a convenient alibi and/or a legitimising means for the prevailing political orthodoxy in education. Educational expansion and hence increased funding of the educational sector were argued on the basis of human capital theory (Schultz, 1963; Bowen, 1964) and of the utilisation of the latent pool of talents. The comprehensive school movement drew support from sociological research findings (Halsey *et al.*, 1961). Technical assistance programmes to Third World countries were also given the blessings of technocrats and several academic experts prior to their approval (UNESCO, 1972; Adams & Bjork, 1971).

The Decline of the Search for an All-Embracing Paradigm

By the mid-1970s the scientific approach of the 1960s to comparative education lost its momentum. Developments in the real world and in academia may be held responsible for the decline of its appeal.

In the first place, many promises – social justice and mobility, uninterrupted economic growth, elimination of underdevelopment – were not kept: ‘scientific’ research and planning had failed to live up to their reassurances as to the righteousness and the effectiveness of their policy proposals (Húsen, 1982). The hard facts of life had in practice rendered unreliable all the grandiloquent statements about the objective, infallible and positive character of the scientific approach, thus undermining the very foundations of its reputation. Scientific comparative education was not in this sense better suited for the job than other alternative methodological approaches. This explains perhaps why so many different approaches and perspectives found a place in comparative education during the following decades.

A second reason for the decline of the supremacy of the scientific method in comparative education should be sought in the changing epistemological pattern in the natural sciences. The quantum mechanics paradigm in physics was suggesting that god might eventually play dice; uncertainty and perhaps chaos rather than the rule of law might be the order of the day in nature. And if this was true for physics, then social sciences (and comparative education) could not hope for anything more. The scientific method could not claim supremacy on epistemological and practical grounds over other alternative approaches.

In addition, the post-modern climate, the devaluing of grand theories into grand narratives, favoured in the social sciences the development of new cognitive domains, new theories and new approaches; despite their more qualitative, participatory or subjective character, these approaches were given an equivalent academic status. Thus, comparative education itself saw the emergence of new approaches and methodologies that were disputing and negating the dominance of the scientific paradigm of the 1960s; academics’ inclination to explore new regimes of truth had certainly played its role. Already by the 1980s one could rightfully suggest that ‘there are now many schools of thought in comparative education and none has dominance’ (Altbach, 1991: 493); consequently it would be more accurate to speak today about comparative educations rather than about comparative education (Cowen, 2000).

The decline of 'scientific' comparative education does not certainly imply that it has lost all its influence or its adherents. After all, 'there are always some men who cling to one or another of the older views' (Kuhn, 1970: 19). This is even more true for those past paradigms that had served their stakeholders well. In this sense, the covariational, quantitative and empirical sort of comparative education has consistently served politicians well. They have repeatedly relied on it for the legitimation and promotion of their preconceived policies. The longevity of the IEA studies and the influence programmes like PISA have on policy making bear witness to this fact.

Coda

Referring to the development of national systems of education Hans had argued that every system corresponds to a complex edifice of various architectural styles, each related to the historical period its different apartments were built (Hans, 1958: 10).

The metaphor seems somehow appropriate for the development of comparative education too. Its forefathers had discovered a privileged site for educational study amidst the marshy land of nineteenth century educational borrowing. They had decided to build an edifice on it that would contribute to the utilisation of its fertile ground; to a better understanding of the interplay between society and education through history. When later on difficulties arose, their successors, equipped with new 'scientific technologies', built a new and presumably stronger estate. Ever since, new buildings have been erected, each following different architectural styles and contributing to an allegedly better utilisation of the land.

From the very beginning some of those buildings were occupied by tenants related to policy making. Yet the rest remain in the hands of the academic community and are still being expanded. Fortunately enough, they constitute the habitat of criticism, innovative thinking and creativity; the place where *episteme*, the art of endless, laborious but intellectually rewarding search for truth resides.

THEORIES OF THE STATE, EDUCATIONAL EXPANSION, DEVELOPMENT, AND GLOBALIZATIONS: MARXIAN AND CRITICAL APPROACHES

Liliana Esther Olmos and Carlos Alberto Torres

Introduction

Education has in modern times been situated within the nation-state. It has been shaped by the demands within the state to prepare labor for participation in its economy and to prepare citizens to participate in the polity. This approximate congruence of nation-state and formalized education becomes problematic as globalization processes place limits on state autonomy and national sovereignty, affecting education in various ways.

The twentieth century has been marked by the expansion of educational opportunities worldwide. It has been the century of education, and the role of the state in the promotion of public education has been decisive. Yet, at the millennium's turn efforts to diminish the role of the state were rapidly changing education, especially in terms of its role in democracy.

Theories of the state, the nature of the state, and the nature of public policy have substantive importance for an understanding of the political nature of education and public policy formation. Defining the "real" problems of education and the most appropriate (e.g., cost-effective, ethically acceptable, and legitimate) solutions depends greatly on the theories of the state that underpin, justify, and guide the educational diagnosis and proposed solutions. There is, however, a permanent challenge here. As Martin Carnoy (1992) has argued, most analyses of educational problems have implicit in them a theory of the state but seldom are the fundamentals of that theory recognized or spelled out in educational research and practice. Becoming self-reflective about our own assumptions seems to be a precondition for solid scholarship.

Therefore, this chapter briefly reviews classical theories of the relationship between the state and education, in particular neoliberal theories, and Marxist critiques of these formulations. Obviously, any analysis of the relationships between education and the state should take into account the multilayered, complex, and dynamic nature of these relationships, revealing the multitude of tensions and contradictions that emerge out of the historical and social force buffeting political and educational institutions. This comment is due to the weaknesses of some theories, which often tend to assume a single causal factor of educational expansion, and ignore the importance, which the state,

operating under concrete structural, political, and historical constraints, attaches to the contribution that education might make to its functions in the area of accumulation and legitimation. Further, most of these theories lack rootedness in specific historical context of particular educational systems and their development, a historical sensitivity which is indispensable for the formulation of sound theoretical explanations of educational expansion. On the other side, the type of criticism represented by Marxism is unique in that it includes a self-critical concept since Marxism is a theory of history, which in turn, tries to offer a history of theory. P. Anderson cited in Amadeo (2006), page 53.

Finally, to draw attention to the sort of questions concerning education and the state which are brought into focus by the argument presented here, the analysis is placed in the context of the globalization of economies, and cultures, using as a case in point the educational experience of the last decades within Latin American societies.

Educational Expansion and the State

We have argued elsewhere against grand theories explaining educational expansion, whether they are functional or world system theories. The approach we attempt to develop concentrates on the historical circumstances of capital accumulation and political legitimation in specific countries, and their influences on educational growth. This approach explains how various Third World countries have developed dual educational systems—one for the wealthier group, and the other for the subordinate ones. We exemplify our approach by the Latin American experience of social change and educational expansion. Yet, the conclusions we draw and the further research questions we pose are applicable to many countries.

In the last 30 years educational expansion has attracted considerable attention from Weberian, Functionalist, and Marxist scholars alike. Although these analyses have focused largely on the European and North-American experience, some attempts have been made in more recent years to examine and explain patterns of educational expansion in countries of the so-called Third World.

This latter line of inquiry has been guided by a primary concern with the impact of the world system of which each nation-state in the contemporary world is a constituent element.

In conceptualizing the world as a single social system, it is argued that its organizational and cultural milieu penetrates the various structural characteristics of all countries. The key elements of this shared culture are: (1) common national economic development goals; (2) an educated citizenry seen as a prized asset from all political perspectives; (3) the belief that individuals and countries are not static but improvable; and (4) that in the context of a capitalist world economy “development means success in economic competition.” The causes of this universal educational expansion are therefore seen to lie in characteristics of the contemporary world system, which affect all nations simultaneously in similar ways.

However, this particular argument and body of literature suffer from a number of problems. It simply postulates the existence of a world historical transformation which

gave rise to it, and why it is that one is justified in treating educational systems and their recent development as being autonomous of or discontinuous with their prewar legacy. It is as if some sort of a “Big Bang” brought into being a unique world system and the associated patterns of educational developments. The causes and consequences of educational expansion prior to 1945 are treated as irrelevant for explaining later developments. Likewise, educational reform in societies undergoing rapid social transformation has attracted the attention of scholars (Carnoy & Samoff, 1990; Torres, 1991; Ginsburg, 1991).

Capital Accumulation and Educational Development

It is true that most “Third World” societies, including those which have achieved independent nationhood in the wake of postwar decolonization, have been subjected to the historical experience of underdevelopment and, thus, share certain structural characteristics relative to the constraints inherent to their economic development and the process of capital accumulation. Yet, it is questionable whether they share, along with the advanced capitalist nations of the world, a common organizational and cultural milieu.

We argue in this chapter that, analytically, it is more fruitful to approach the study of educational development in these societies in relation to the global process of capital accumulation, to which they were subjected under the historically concrete conditions of capitalist expansion and/or colonization. Colonial and postcolonial eras represent two different sets of conditions for capital accumulation and educational development or expansion. While postcolonial expansion of education has been taking place in changed domestic and international context, it is conditioned in important ways by the patterns of educational growth during the colonial period. The study of educational expansion or growth in relation to the process of capital accumulation, as it proceeds at the national and global levels, calls for a political economy framework of analysis. This should systematically explore the historical linkages between the pre- and post-war developments, by focusing on the dynamic interaction between the state, capitalist accumulation and educational expansion.

Political economy’s starting premise is that we can come to know a society’s key structures and understand its diverse and specific social practices by examining the way in which the members of that society produce and reproduce the conditions of their existence. In this perspective, schooling in contemporary societies is treated as a distinct institutional complex with its own diverse and distinct social practices and purposes, but one that is shaped by both the dynamics and contradictions of the capital accumulation process and the power relations between different economic, political, and social groups. Because power relations among groups are expressed in increasingly important ways through a society’s political structures, and more specifically the state, any political economy analysis of the educational system must be based on some implicit or explicit analysis or theory of the purposes or functioning of the democratic state.

The modern state refers to a complex of institutions, such as the government—which means the bureaucracy, the military, the judiciary, and representative assemblies—including provincial and municipal institutions of government. According to the

traditional approach, the liberal democratic state must perform two basic but often contradictory functions: to foster capital accumulation and social harmony and consensus. These “functions” refer to what are merely tendencies at work within the capitalist state. Whether the state meets these requirements, and the manner and the extent to which it is able to do so, is not preordained in the state structure, but is conditioned by the historical specificities attendant upon its operation. While this model of the dual functions of the state might be theoretically adequate for analyzing democratic state, this is not so with respect to policies of the colonial state or, in many cases, the post-colonial one. The colonial state, because of its inherently unrepresentative and coercive character, has been much less concerned with the so-called legitimation function. It follows, therefore, that educational expansion policies pursued by the colonial state cannot fruitfully be interpreted in terms of the contradictory demands of capital accumulation and legitimation. Capital accumulation functions, and minimal requirements of constructing the state apparatus with adequate administrative-coercive capacity, have historically weighed far more heavily in the development of the educational policies of the colonial state.

Indeed, it is necessary to identify different phases in the development of the capitalist accumulation process on a global scale, and then analyze the dynamics of educational expansion nationally, in relation to the timing and mode of insertion of particular societies into the global system. The time and mode of insertion of historically distinct national political economies into the global accumulation process, the legacy of educational systems which predated such insertion, and the social and cultural specificities of their social structures, are the three sets of factors which have been and continue to be crucial in shaping the structure and growth of their educational systems.

Marxism as a Critical Theory

In order to examine such decisive features as the ones developed in this chapter, a brief but necessary explanation about the reasons we have to privilege the Marxian theoretical corpus is required here. Furthermore, how do we understand the significance of going back to such fundamental and irreplaceable source of critical thinking as Marxism? And, if the matter of returning is at hand, why was it that so many of us chose to distance ourselves in the first place and are now coming back to it?

First, the destiny of Marxism as a critical theory—or, in paraphrasing Jean-Paul Sartre cited by Boron, A. *Por el necesario (y demorado) retorno del marxismo*, as the indispensable critical horizon of our time, has been indifferent neither to the changes generated by socialist revolutions nor to the highs and lows of popular wars fought in the twentieth century. We are convinced that a theory of history such as Marxism which in turn offers a history of theory, has survived as an intellectual and political tradition due to two principal factors that are not the only ones but appear to be the most important. The first factor is capitalism’s constant incapacity to confront and resolve the problems and challenges that originated through its own being. As long as the capitalist system proceeds to condemn the growing sector of modern societies to exploitation and all forms of oppression—such as poverty, marginalization, and social

exclusion—and creates nonstop damage to the environment through its brutal commercialization of water, air, and earth, the conditions to pursue an alternative vision for society along with a practical methodology to end these effects will always be present. J. P. Sartre, cited in Boron (2006), page 35.

The second factor is that this theory has demonstrated an unusual capacity to deepen itself in accordance with the historical developments of societies and the struggles for emancipation of those who are exploited and oppressed by the system. Yet, it cannot be ignored how Marxism is negatively affected by the lack of strategic dialogue in terms of a political project capable of unifying and combining the energies, which is one of its central problems that must be resolved if Marxism wants to be retransformed into a philosophy of praxis.

To conclude, we would like to bring back Sartre's analysis of Marxism. This still possesses vigor. In *Questions de Méthode*, the French philosopher affirmed that a philosophy will continue to be efficient as long as the praxis through which it was engendered and sustained remains alive. Once everyone has access to a margin of real freedom from the production of life, Marxism will disappear and a philosophy of freedom will emerge in its place. However, we are devoid of any intellectual tool or concrete experience that would allow us to conceive of this freedom or philosophy. For these reasons, Marxism continues to be the unsurpassable philosophy of our time, as the circumstances that engendered it have yet to be overcome (Amadeo 2006).

Education and the State

The concept of the state has become one of the very few in contemporary social sciences endowed with the capacity to foster a rich theoretical and methodological debate, not to mention the inflamed political controversy raised by its practical existence. It has regained recognition as a key concept in the history of political research. Discussions about theories of the state acquired new vigor in the early 1970s, as a result of debates concerning the Marxist political theory of the state and the work of Antonio Gramsci, and in the 1980s, in mainstream political science discussions of the autonomy of the democratic state. Now, why is the notion of the state so important in an understanding of educational policies and practices? The literature shows that the answer to this question should be drafted in the context of the relationships between education and government, education and the economy, and education and citizenship building. This is in view of the fact that educational systems and practices are sponsored, mandated, organized, and certified by the state, therefore their analysis cannot be separated from role, purpose, and functioning of the government.

However, the relationships among education, politics, and the state cannot be discussed only from the perspective of mainstream political culture. Despite what those advocating “technocratic” or “technicist” views of educational research, curriculum, and educational policy would like to believe education is neither politically neutral nor technically “objective.” As Paulo Freire has consistently claimed in his work, there is an inherent “politicity” of education that has epistemological, analytical, and ethical implications. This politicity relates foremost to the explicit but also the subtle linkages

between education and power. At the same time, it is related to the political nature of the state and public education as contested arenas and sites for exchanges of goods and services and competition involving political-economic projects (Freire, 1994). In summary, prevailing notions of the state held by policymakers and researchers influence the dominant research agenda, the analysis of educational problems, and policy prescriptions. Theories of the state also influence educational research *per se*. At a concrete and practical rather than abstract level, theories of the state held by government coalitions and educational bureaucracies will influence not only research but also the planning and operation of educational systems. Discussions about theories of the state and education encompass a broad range of theories regarding the relationships among education, the state, and civil society. By implication, theories of the state define the nature, purpose, and role of educational research, policy, and practices.

Theories of the state give substance to the range of moral and ethical dimensions (and roles) attributed to education and schooling in the process of cognitive socialization and construction of cultural identities. Moreover, theories of the state (and their precepts regarding the linkages among power, state, and society) will guide the constitution of national, regional, or local educational policies of schooling, including job training programs, and the knowledge that is deemed legitimate and official.

Liberal, Neoconservative, and Neoliberal States

Liberal-pluralist theories of the state conceive this as a political system, as an autonomous political institution independent from the system of production and class structure. The state appears, then as a neutral referee overseeing and regulating the clashes between interest groups and eventually elites competing for resources conflict with the general interest of all citizens or when the state, pursuing independent activities, attempts to modernize society. The liberal view suggests that the state is the collective creation of its individual members, providing a set of common social goods, including defense, education, a legal system, and the means of enforcing that system to all the majority of citizens and legal residents. At this point, we would like to posit the following question: are there any connections between the conservative and the neoliberal state? Taking a world system approach based on Wallerstein's work, the distinction of metropolitan, semiperipheral, and peripheral countries plays an important role in designating the nature of the state. Neoconservative political economy has emerged, partly, as a reaction to welfare states in metropolitan state formations. Many of these state formations have been characterized as industrially advanced societies or late capitalism. Indeed, the majority of neoconservative experiences have taken place in states that have not been historically subject to colonization. Moreover, with few exceptions, these states have not been colonized themselves, profiting from colonizing regions of the world later identified as Third World states.

The notions of neoliberalism and the neoliberal state appear to be "exported" from the center to the periphery and semiperiphery. The point can be illustrated with a discussion of Latin America and regions of the South in the last few decades. No doubt, a neoliberal ideology and narrative are consolidated in the central countries. Given the

implications of the liberal past of metropolitan societies, the specific debates within the political parties and the influence of neoconservative economics in globalization, the notion of neoliberalism in central countries appears almost interchangeable with the notion of neoconservatism in political economy. Lomnitz and Melnick (1991) argue that, historically and philosophically, neoliberalism has been associated with structural adjustment programs. Structural adjustment, in turn, is usually described as a broad range of policies recommended by the World Bank, the International Monetary Fund, and other financial organizations. Although the World Bank differentiates among stabilization, structural adjustment, and adjustment policies, it acknowledges that the general use of these terms “is often imprecise and inconsistent” (Samoff, 1990).

Neoliberalism offers similar prescriptions. The politics of neoliberalism, when transported to the countries of the periphery, constitute a set of proposals that refer to the conditions of the countries of the South in the international context, particularly in the division of labor. Neoliberalism strives to pass the cost of educational services to clients through user fees, increasing the participation of the private sector in education (i.e., privatization), and promoting decentralization of educational services as a means of redefining the power and educational relations among federal, provincial, and municipal governments. These standard policy prescriptions overlap heavily with neoconservatism (Torres, 2007).

Changes in state formation entail a change in the production of hegemony and commonsense interpretations of everyday life and, particularly, a change in the political alliances controlling the state, from liberalism to neoconservative and neoliberalism. Replacing the role of the state with the logic of the market in determining educational policy is criticized as a class strategy in the neoliberal state (Ball, 1993). A similar argument is made about the withdrawal of state investment in public education in Latin America and how that would affect the constitution of citizens as pedagogical subjects (Torres & Puiggrós, 1995). Changes in the labor process relate to the move away from a mode of production defined as the transformation of Fordism to a post-Fordist model (with implications for the process of skilling and deskilling of the labor force and the logic of technical control in curriculum) (Apple, 1982).

From the Nation-State to Globalizations: A Critical Perspective

Despite their increasing historical specificity, and because of their normative and analytical orientations, critical perspectives have, by and large, focused on the nation-state as the locus of politics and education. The notion of globalization, however, has transformed the debate, raising the stakes of emancipatory politics in education.

Globalization has been defined as “the intensification of worldwide social relations which link distant localities in such a way that local happenings are shaped by events occurring many miles away and vice versa” (Held, 1991). Among other things, Held suggests that globalization is the product of the emergence of a global economy, expansion of transnational linkages between economic units creating new forms of collective decision making, development of intergovernmental and quasi-supranational institutions, intensifications of transnational communications, and the creation of new

regional and military orders. The process of globalization is seen as blurring national boundaries, shifting solidarities within and between nation-states, and deeply affecting the identities of national and interest groups. Neil Smelser (1993) captures the spirit of this theme quite well.

A convenient starting-point for depicting the world situation is to consider the status of the nation-state. Once commonly supposed to be the natural and sovereign focus of the loyalty and solidarity of its citizens, this idea of the state has recently been challenged with respect to all of these constituent elements. The international boundaries of the state have become permeable through the greater globalization of production, trade, finance, and culture with a resultant loss of control of all states over their own fortunes. The sovereignty of states has been further compromised through shifting patterns of regional political federations and alliances. At the sub-national level, the state has found itself challenged by the efflorescence and revitalization of solidarity groupings with multiple bases—regional, linguistic, religious, ethnic, gender, and solidarity. All of these compete with the state for the loyalties of peoples and sometimes for jurisdiction over territory. In a word, the contemporary state has been pressured from both above and below by contested boundaries and shifting solidarities.

The capitalist state, although territorially defined, was born and develops a loose network of interrelated and overlapping jurisdictions. The regulatory framework for corporate capitalism which emerged from the last part of the nineteenth century was based on the nation-state but involved emulation and transplantation of forms, as well as international coordination; and it facilitated international ownership of capital through the transnational corporation which became the dominant form in the twentieth century. Transnational corporations have favored minimal international coordination while strongly supporting the national state, since they can take advantage of regulatory differences and loopholes. Processes of international coordination of states relying on national legitimation, have taken the form of bureaucratic-administrative bargaining through a motley network of informal structures as well as the more grand organizations. The growing globalization of social reactions has put increasing pressure on both national and international state structures (Ruccio et al., 1991)

The growing internationalization of the state is still an open quo terms of its scope and dynamics. Likewise, the implications of this internationalization and globalization for educational policies, textbooks, and curriculum are hitherto lacking empirical and theoretical research. There are exceptions. In an eight-country study of reforms of teacher education, Popkewitz and Pereyra (1993) argued that international organizations, such as the Organization for Economic Cooperation and Development (OECD); and the European community are playing crucial roles in promoting changes in regulations governing teacher education.

The role of international organizations in the process of globalization and the nation-state has been aptly discussed by Joel Samoff, who studied the World Bank's logic of lending in education. By his account, the World Bank is one of the most prominent regulatory agencies of the capitalist system. Samoff argues persuasively that the World Bank is a major player in an intellectual and financial complex pursuing the transnationalization of knowledge and expertise, using a community of experts for hire in a process where there is a strong confluence of research and educational financing. The world is seen as having a pivotal role in the network of power and

decision making in education worldwide, influencing in peculiar ways research and policy-making in developing countries as well as influencing the international discourse in education by different means. First and foremost is the commissioning of long-term research with abundant budgets. This terminology, as presented in most of the World Bank's documents, is based mostly on a neoclassical economy of education, human capital theory, and a theory of the firm applied to education. Through its financial weight and operational reach, the World Bank also influences the methods of analysis considered appropriate and legitimate (e.g. cost-benefit analysis, input-output analysis, and rate of return), defends a technocratic instrumental rationality rather than a politically and historically informed policy orientation, and confers legitimacy to hypotheses and research findings that its experts deem useful and necessary for educational investment and development. Samoff (1992, 1993) would agree that there is a diversity of theoretical perspectives within the ranks of the World Bank's researchers. But he points out that the organization's logic is implacably applied in the context of its lending and that the workings of its managers in charge of lending are distant from the theoretical and empirical analysis of its researchers. The World Bank's logic of analysis cannot be characterized as pluralistic. Although not free from tensions and contradictions, the organization is quite monolithic (Samoff, 1992, 1993). Similarly, in studying the influence of the World Bank in higher education throughout the world, Daniel Schugurensky has argued that the World Bank plays a role at an international level similar to the one played by the Business Roundtable in the United States with its agenda for educational reform. In short, there is an elective affinity between the policies promoted by the World Bank and the many neoliberal and neoconservative proposals emanating from the Business Roundtable (Schugurensky, 1994)

The State and Education in Latin America

We offer here a brief account of historical and theoretical context for a discussion on the state and education expansion in the Latin American region. The nineteenth-century liberal state, and the diverse state models that emerged in the wake of the struggles of the 1920s and the depression of the 1930s, granted to public education systems a major role in the integration and legitimation of the political systems and the modernization of Latin American countries. As part of its development policies the state extended social benefits to vast sectors of the population, particularly in Argentina, Costa Rica, and Mexico. Education played a key role in these social programs, because mass schooling was viewed as a means of building a responsible citizen, skilled labor, and increasing social mobility. In the early 1960s, human capital theories and educational planning justified educational expansion not only as a good investment in skill training but also as a prerequisite for liberal democracy.

The Latin American educational expansion during the early phase of industrialization in the 1960s accounts for the highest rates of educational growth in the world. Between 1960 and 1970, the indices of growth for higher education and secondary education were 247.9% and 258.3%, after which it grew by only 167.6%, while the illiteracy rate remained more or less constant in most countries of the area. One

study of the late 1970s shows a fundamental continuity in this pattern of educational development. Ernesto Schiefelbein has argued that in the last four decades of the last century, Latin America made significant progress toward democracy by “(i) expanding access to education for most the children reaching school age; (ii) extending the years of schooling; (iii) improving timely entrance to school, (iv) providing early care to an increasing number of deprived children, and (v) increasing the provision of minimum inputs and eliminating tracks for social levels.” However, changes took place against this background, and were perhaps the result of a new global economy which was emerging and operated in very different ways from the former industrial economy. The old economy was based on high volume and highly standardized production with a few managers controlling the production process from above and a great number of workers following orders. Because of advances in transportation and communications technology and the growth of service industry, production has become fragmented around the world. The new global economy is more fluid and flexible, with multiple lines of power and decision making thus, while the public education system in the old capitalist order was oriented toward the production of a disciplined and reliable work force, the new global economy seems to have redefined the goals of public educations in development. The new roles for public education (and for many, the future of public education) is at stake in the current debates about education policy.

From a political economy of education perspective, the performance of the economy is a major issue underpinning educational policies. The question is to what extent the prescribed recipes of structural adjustment as a cure to the economic malaise will help or hinder educational expansion, quality of education, and equality of educational opportunity in the region. This is the bedrock underscoring the political behavior of the main actors concerned with educational services in Latin America today, particularly teachers’ organizations, the neoliberal state and its agencies, and the role of international organizations, particularly the World Bank.

It is imperative to situate the national and regional educational policies of Latin America within the context of global economic, political, and social changes of the past years. The current regional context was affected by innumerable changes including the rise of the newly industrialized countries in Asia and the Pacific rim, and its impact on the models of economic development in Latin America; the promise of consolidation of regional economic markets (European Economic Commission, NAFTA, and MERCOSUR); the intensification of competition among the major industrial powers of Germany, Japan, and the United States; the opening of Eastern Europe; and the resurgences of regional ethnic and religious conflicts. These changes and contradictions were increasingly related to the process of globalization of economies, cultures, and societies, showing how very powerful are structural forces involved in education at times of severe crisis and re-structuring of policy priorities and systems.

State Corporatism and Theories

Public education plays a major role in the legitimation of the political systems and the integrations and modernization of countries in Latin America in the context of corporatism

and dependency. Although the “dependency perspective” should be placed in the context of broad schools of development as modernization, postimperialism, and interactive local political economy perspective among others, it focuses on the structure of international capitalism and the lack of availability of capital for autonomous expansion of a less developed economy. Modernization focuses on the nature and characteristics of the social structure of less developed countries as causes of underdevelopment. Postimperialism theories attempt to explain underdevelopment as part of a process of transnational class formation in the developing world. Finally the perspective that focuses on the interaction of social domestic forces using a modern political economy emphasizes that the complex interaction of domestic socioeconomic and political trends determine policy outcomes, insisting on the centrality of economic pressures by domestic socioeconomic actors in the determination of policy options and outcomes.

Political economists of education and political sociologists from a dependency perspective have helped to identify the institutional identity of the state as crucial in understanding the role education has played in development and social change. The theory of the “conditioned states” in the Third World, expanding upon and clarifying the notion of the dependent state, argues that the state is conditioned “by the nature of the peripheral role that its economy plays in the world system and the significant (post-feudal) elements in its own political system”. Therefore, Latin American “conditioned states” have not been able to carry out their public functions properly for a number of reasons. On the one hand, the fragility of local economies made local dominant groups unwilling to allow the pluralist participation of the masses in the selection of the state bureaucracy. On the other hand, since the state historically has been identified by the popular sectors more as a pact of domination by the dominant classes, or a surrogate state, it has not been seen as an independent state working on behalf of the citizenry.

Another question is the ability of the state to consolidate the nation and the market. Since the boundaries of the market are externally defined by the presence of external powers and multinational corporations, the definition of the nation is continually and historically re-elaborated by a complex matrix of exogenous-endogenous processes. More often than not the conditioned state has little control over its own political economy dynamics.

While the notion of dependency, dependent-development, and the conditioned state set the tone for a discussion on the nature of the state in Latin America, drawing from the tradition of political corporatism, the notion of state corporatism from the political sociology of education has been employed to study the peculiar characteristics of political regimes in the region, in particular educational policy formation in Mexico.

Education has played a fundamental role in the legitimation of the postrevolutionary state, and has contributed to state hegemony in Mexico. It has been argued that the corporatist nature of the postrevolutionary state has deeply conditioned the way educational policy has been organized, implemented, and evaluated, and that education (particularly adult education) in Mexico is part of a comprehensive project of compensatory legitimation. While the Mexican case is perhaps too specific, it could be argued that historical changes in the patterns of relationships between state and society during this century created the conditions for the widespread implementation of corporatist arrangements, and the development of corporatist states.

The role of the conditioned state continues to be problematic for democracy and public education in the region. While we have argued that the institutional identity of the state is crucial in understanding the role education has played in development and social change, the notion of the dependent or “conditioned” state helps to understand not only the contradictions in public policy formation, but also the disparate roles and functions that the Latin American states play in the context of peripheral capitalism. Conditioned by the dynamic of metropolitan capitalism, the significant noncapitalist (although perhaps postfeudal) elements in its own political system, and the political alliance in power, the nature of the democratic state in the region continues to pose serious constraints to the political and economic democratization of civil societies. This is more so when, despite the political shortcomings of the Latin American democracies and their limitations in endowments and resources, the liberal state in the region attempted to develop a system of public education that provided access and permanence to the system of public education that provided access and permanence to the system to vast sectors of the population, including the poor. The policy rationale was clearly synthesized by the premise that the state should “educate the sovereign”. A critical extension but also de-construction of this premise emerged in the 1960s with the notion of a pedagogy of the oppressed, conscientization, and popular education. The current debate in the region is, on the one hand, whether the systematic withdraw of resources from public education under the political economy of neoliberalism has deeply affected the traditional educational role of the states, the performance of the systems vis-à-vis equality of educational opportunity and quality of education, and by implication the nature of the democratic pact. On the other hand, the prevailing theories and methodologies and the political–technical rationale for educational planning, are seen as subsidiary to the main goals of neoliberalism. These goals were expressed by international institutions like the IMF and World Bank with their political economy of conditionalities and policy references, but were also accepted and graciously implemented by neoliberal states in the region. The question is whether, given the processes of globalization, these internationally induced policies are compatible with fundamental notions of democratic accountability national sovereignty, and community empowerment. The question about the nature of the state and public policy is also a question about the future of public education in Latin America.

Conclusion

Current social, political, and economic changes in Latin America underscore the pace, texture, and scope of educational development, educational quality, and the relevance of education. In this context, educational planners and communities deal with the implications of the lack of economic growth in the 1980s and 1990s, the growing external debt, increasing fiscal constraints, and intended and unintended impacts of structural adjustment of economies and neoliberal states and policies. Alas, the relationships between education and social change continue to be revisited by those seeking educational reform, but the challenges of poverty remain seemingly intractable for public policies—especially education—and democracy.

It is in the framework of this historical dialectical totality where the comprehension of neoliberalism and globalization should insert themselves as foundational phenomena of a new articulation of capitalistic domination, as primogenital forces from an intent of rearticulating the relationships between the economic-technical subsystems and the social-political-institutional sphere with a new qualitative connection among them.

Globalization is a sine qua non condition for the modern day phase of capitalism, given the widespread movement of capital and the necessity to squash/destroy worker resistance throughout the planet. One must remember that globalization is constructed from the pillars of liberalization of the flow of capital, deregulation (flexibilization in the capital-work relationship and liquidation of the social security) and competitiveness—the last one understood as the unrestricted application of the two previous requisites.

The crisis of the neoliberal model does not follow a symmetric rhythm thus, given the particularity of Latin America in historic cycles, it is very likely that this model intends to implant itself in a phase in which it has lost international sustentation. A large spectrum of alliances should be constructed, all of their efforts concentrated, to coincide with the anticapitalist and libertarian character from the construction of an alternative to neoliberalism and exclusionary globalization.

As Daniel Bensaid affirms, Marxist thought flourished as a result of the rigorous research that demonstrates the extent to which the spectrums of Marxism impact the present. The new century appears to be a promising period of creativity for the tradition of this theoretical framework.

The Marxist tradition as a social and political science of emancipation tied with the sciences of current times, as part of a cognitive process of transformation and joint action, is an interwoven praxis which should be recuperated. To reconstruct this critical reason in the face of the growth of cynical reason is essential.

Constructing partial synthesis and successive approximations, reconstructing the dialectic as a method and way of knowing, and associating the “cold” side of Marxism (science) with its “hot” phase (utopia), knowledge and praxis, will be how the creation and revolutionary interpretation of reality develops, so that Marxism continues to be as Gramsci said, a “Philosophy of Praxis.”

COMPARATIVE EDUCATION IN EUROPE

Wolfgang Mitter

Historical Retrospect

Contextualising comparative education in the regional framework of Europe cogently leads to the basic structural principle that has determined the mainstream of European history since the early Middle Ages: the dichotomy between diversity and unity. This basic argument explains that this introductory chapter takes up this theme and uses it as the continuous motif of the present analysis on the whole. It seems that the facts and trends that indicate diversity can be asserted as the *stronger* pole at first sight. This assumption has exercised its significant impact on comparative education throughout the development of this discipline. Consequently, our main attention is directed to the geographical, institutional and thematic *map* of Europe with its distinctive working places, whenever we are invited to investigate events, trends or attainments in any comparative approach: universities, research institutes, documentation centres, academic societies, regional units and, finally, states.

It is this latter kind of territorial limitation that has become the most significant determinant of comparative education from its origin to the threshold of the twenty-first century. May it suffice to trace the history of the discipline back to the beginning of the nineteenth century, when Marc-Antoine Jullien de Paris designed his project dealing with a plan of comparing state education systems all over Europe within the outer borders of the *Holy Alliance* that claimed to lay the ground for a peaceful order after the Napoleonic wars. (Jullien, 1992; Vandaele, 1993). However, Jullien's idea was overlapped and eventually replaced by the political and ideological *alliance of state and nation*, which should become the focus of comparative educational studies, namely in the configuration of the nation state, as an essential heritage of the French Revolution. It has gradually expanded from its emergence throughout the nineteenth and twentieth centuries. The current trends, however, signalise the end of the modern nation state's monopolising *educational sovereignty* in favour of competitors in the regional and global dimensions (Mitter, 2004; Bray *et al.*, 2007).

In accordance with the dominance of Europe in producing the conditions and in setting the norms for the progress of science and technology as well as (institutionalised) education all over the 'rest of the world', the origin of comparative education on that continent has exercised enormous influence on the expansion of the discipline in substantial, methodological and organisational terms. In the course of the twentieth century,

in particular since the emigration of prominent educationists from Nazi Germany and Central Europe in the 1930s, the focal position of Europe in comparative education studies has been continuously contested and finally displaced by rising competitors, the 'counter trend' starting in northern America, where the origins of the discipline date back to the nineteenth century, and spreading to further world regions, in particular to eastern Asia.

Though focusing their attention on the *diversity* pole, embodied by particular features of national education systems, European comparativists have never abandoned their interest in their *commonalities*. Moreover, some prominent figures among them have felt dedicated to the overarching idea of a 'European unity' to be derived from spiritual and material events and developments in pre-modern periods, as well as from contemporary trends in science and philosophy, literature, music and the fine arts. In the history of comparative education this 'European idea' was expressly reflected in the theories of the *driving forces* expressing convergences in the interrelations of national education systems and cultural configurations. Taken as a whole, all those trends have laid the ground for the fundamental tension between universalism and cultural pluralism which we are aware of in the globalising world of today as the modern manifestation of the perennial dichotomy mentioned at the beginning.

The European history of comparative education as an academic discipline (Hilker, 1962) began in London, when Michael Sadler devised his concept of exploring education systems and trends abroad and of comparing them with the education system of his home country. In his considerations Germany was the favourite subject of reference. To implement his concept, he convinced the British government to establish the *Office of Special Inquiries and Reports*. Taken as a whole, his engagement was aimed at providing the educational authorities of his country with advice to improve education and schooling (Higginson, 1979). Sadler's 'European' initiative, however, had been preceded at universities in the United States with Peter Sandiford and Paul Monroe as pioneering researchers and teachers.

Moreover, outlining this *academic* start would be incomplete without its inclusion of the 'preparatory' period of comparative education pervading the nineteenth century. It seems to be useful to refer to these three 'precursors' (Hilker, 1962; Vandaele, 1993):

- (a) Marc-Antoine Jullien's *theoretical* approach which, though incomplete and forgotten for decades, anticipated modern approaches to collecting and comparing data about items of national education systems for the sake of harmonising and improving them on the base of empirical evidence.
- (b) The *policy-oriented* approach materialised by the thorough and reflective reports of 'educational travellers', school inspectors as a rule, who went abroad to study documents and to talk to ministers, administrators, headmasters, teachers and higher education representatives, also served as support for educational reforms, in this case related to their home countries only.
- (c) Wilhelm Dilthey's *philosophical* approach resulted from his reflections on the use of comparing education systems on the base of historical studies and the application of hermeneutic-interpretive methodology.

Jullien's *oeuvre* was theoretically based, insofar as he deliberately devised a consistent and well-structured system of grids as base for his intended inquiries. In this approach he acted as a typical representative of rationalism and enlightenment and an early precursor of what has developed into the positivist model in comparative education. Dilthey, on the other side of the spectrum, paved the way for the humanistic (*geisteswissenschaftlich*) stream of the discipline. Finally, the travellers' projects give insight into a combination of both contrasting approaches. By their method to explore statistical surveys and legal documents they have proved to be Jullien's followers, though limiting their inquiries to two or few national education systems and without knowing his *oeuvre*. With him they also shared the aim of making contributions to the improvement of really existing manifestations of education. On the other hand the analyses of their experiences and their efforts to contextualise them in the socio-political and cultural environments of the education systems explored bear witness of their own academic background in the humanities and their expertise in applying historical and hermeneutic approaches.

Criteria of Analysis

The following set of criteria is proposed as an outline for describing the current state of comparative education, as it has come out of the twentieth century. Focusing on European particularities does not mean, of course, concluding that these selected criteria are meaningful with regard to Europe only. The aforementioned worldwide expansion of the discipline indicates their trans-European validity.

The 'European Map'

The map of Europe mirrors the diversity of extension and strength of comparative education with special regard to the territorial location of universities and research institutes. The following survey cannot, of course, claim any completeness, but is presented to give an exemplary insight into the whole scene (Wilson, 1994; Watson, 1998; Paulston, 1999; Mitter, 2005). As mentioned above, the start was made in *Great Britain*. Michael Sadler's legacy was taken up by the Institute of Education at the University of London whose history has been associated with a good number of prominent scholars: Joseph Lauwerys, Nicholas Hans, Brian Holmes, Janusz Tomiak, Robert Cowen and Martin McLean. Other universities joined that trend: King's College in London (Edmund King), Oxford (William Halls, David Phillips), Cambridge (Witold Tulasiewicz), Reading (Vernon Mallinson, O. H. Dobinson, Keith Watson), Manchester (Raymond Ryba), Leeds (Margaret Sutherland), Hull (Colin Brock), Edinburgh (Nigel Grant), Warwick (Rosemary Preston). In *Germany* as the second focal country, the first period was represented by the individual contributions of Friedrich Schneider and Franz Hilker, while their successors were in charge of university chairs or independent research institutes: University of Hamburg (Walther Merck, Gottfried Hausmann, Neville Postlethwaite, Hans-Peter Schäfer), University of Marburg (Leonhard Froese), University of Heidelberg (Hermann Röhrs, Volker Lenhart), University of Bochum (Oskar Anweiler, Christel Adick), University of Münster (Detlev Glowka, Marianne Krüger-Potratz), German

Institute for International Educational Research in Frankfurt am Main (Walter Schultze, Wolfgang Mitter), Max Planck Institute for Educational Research in Berlin (Saul Robinsohn, Dietrich Goldschmidt). Further universities followed, though restricted to individual chairs where comparative education has been as a component of 'general education' (educational foundations) until today. The reunification of Germany opened new chances for the discipline in the Eastern part, just when the main institutions in the Western part of the country had to cope with structural and financial restrictions or even closings. Consequently, the 'torch' was passed to the East, where the Humboldt University with Jürgen Schriewer as Director of the Institute of Comparative Education and Jürgen Henze as Professor has developed into an exceptional place of comparative education. Corresponding chairs, founded at the University of Leipzig (Wolfgang Hörner) and the Technical University of Dresden (Diethmar Waterkamp) have reinforced this recent start. In this context brief attention should be devoted to efforts that had been undertaken in the former *German Democratic Republic* to establish a 'Marxist-Leninist Comparative Pedagogy' with Werner Kienitz and Hans-Georg Hofmann as leading representatives. Those efforts, however, suffered under continual restrictions due to the changing ideological and political pressures by the communist regime and came to an end with the republic itself.

From the 1960s onwards the developments in Great Britain and Germany were paralleled in other European countries. Here the list should be opened with *France* that had been within the 'inner circle' from the beginning with the *Centre International d'Études Pédagogiques* (Sèvres) as stimulating and hosting institution, above all under Edemée Hatinguingais' directorship. The 1970s and 1980s were characterised by Michel Debauvais' extended activities, succeeded in recent years by Francois Orivel and Jean-Michel Leclerq. Besides Lê Thán Khôi's comparative reflections, based on his comprehensive reference to cultural history and sociology, needs to be mentioned as an independent contribution to comparative education (Lê Thán Khôi, 1981). While, in recent years, comparative education in Great Britain and Germany had to cope with institutional reorganisation and budgetary curtailments, other parts of Europe revealed new initiatives; some of them have definitely made considerable progress during the past decades. As for western Europe, the following list signalises this advancement: *Italy* (Lamberto Borghi, Aldo Visalberghi, Mauro Laeng, Vittorio Telmon, Donatella Palomba), *Spain* (Victor Garcia-Hoz, Juan Tusquets, Ricardo Marin, José Luis Garcia Garrido, Miguel Pereyra), the *Netherlands* (Josep Branger, Elzo Velema, Sylvia van de Bunt-Kokhuis), *Belgium* (Cyriel de Keyser, Henk Vandaele, Willy Wielemans), finally the *Nordic* countries (Thyge Winther-Jensen, Torsten Harbo, Reijo Raivola), on the solid ground of Torsten Husén's comprehensive and creative initiatives in transnational research and co-operation. Among the South European 'newcomers' *Greece* has asserted a stable place (Andreas Kazamias, Dimitrios Mattheou), in this position followed by *Malta* (Ronald Sultana). Comparative education in the Soviet Bloc could not establish itself as a truly scientific discipline because of changing interventions by the ruling party authorities, as was already mentioned in the context of the GDR's contribution. However, a few remarkable initiatives could be observed nevertheless in the *Soviet Union* (Zoya Mal'kova, Boris Wul'fsson), *Poland* (Mieczysław Pęcherski), *Czechoslovakia* (František Singule), *Hungary* (Magda Illés) and *Bulgaria* (Najden

Chakarov). Following the revolutionary changes in the beginning of the 1990s there have been new starts in Central and Eastern Europe, namely in Bulgaria (Nikolay Popov), the Czech Republic (Jiří Kotásek, Jan Průcha, Eliška Walterová), Hungary (Tarrás Kozma) and Poland (Ryszard Pachociński Józef Kuzma). Finally, the discipline might not have reached its current position without the continuous support it has received from the big international world organisations, mainly from UNESCO and its institutes in Paris (IIEP), Geneva (IBE) and Hamburg (UIE, now ILL/Institute for Lifelong Learning). It proved its efficiency on various occasions, in particular with regard to the organisation of conferences and meetings.

Academic Associations

Progress, success and survival of comparative education in Europe must be certainly ascribed to the strategic efforts of active and far-sighted persons and the existence of institutionalised working places (Cowen, 1980). These assets, however, needed reinforcement to be provided by professional associations. The history of the discipline gives evidence of various efforts aimed at constituting, developing and asserting comparative education as well as at representing 'European achievements' to the colleagues and competitors in the 'rest of the world'. On the whole the strategies, however, have been neither equal nor consistent, as regards individual intentions and decisions. Furthermore, they have depended on specific actions and circumstances, according to the fundamental dichotomy between unity and diversity. Surprisingly enough the beginning has been marked by the foundation of the *Comparative Education Society in Europe* as a transnational association in 1961, resulting from preparatory discussions and activities of comparativists from several European countries, supported by colleagues from overseas, in particular northern America. The decision for this comprehensive model, even confirmed by the principle of individual membership and against the alternative of any federal and nation-based structure, may be interpreted by the founding-fathers' preference for an association which should be both independent of political influence and 'elitist' which included hesitation in opening it to a clientèle of 'practitioners'. It is true that both criteria have been loosened in the course of the past decades in terms of membership and openness to practice-oriented persons (predominantly from the areas of educational policy and planning) and themes, but they have not entirely disappeared from the agenda of CESE's policies and may be recognised as a, though modified, trademark of the Society until today. The approaches to surrounding CESE with national *Sections* in Great Britain and Germany, immediately following CESE's foundation did not prove to be solid enough. Both 'off-springs' were, formally transformed into nation-oriented associations. It is only the *Italian Section of CESE* which has remained as a survivor of that organisational type.

Instead, CESE has been increasingly confronted with the constitution of competing societies, mostly based on the principles of nationality, either as independent organisations like in most countries (Bulgaria, Great Britain, Greece, Poland, Russia, Spain and, recently, Turkey), or sections of 'pedagogic societies' (Czech Republic, Germany, Hungary). Alternative strategies have led to the foundation of the regional *Nordic Society* (including Denmark, Finland, Norway and Sweden) as well as linguistically

based associations with transnational catchment areas, such as the *Dutch-speaking Society of Comparative Education* addressing their native speakers in Belgium and the Netherlands and the *Association Francophone d'éducation comparée* (AFEC) with its membership in Europe and overseas. In recent years the region-oriented trend seems to have reached its strongest manifestation by the foundation of the *Mediterranean Society of Comparative Education* with its branches spread over Southern Europe, Northern Africa and the Middle East, thanks to Giovanni Pampanini's exceptional initiative. The local model of the *London Association of Comparative Education* (LACE) has existed only as a temporary organisation (during the mid-1970s), while a new alternative type (*Association française pour le développement de l'éducation comparée et des échanges*) has emerged in France with emphasis on the dissemination of comparative education into the practice-bound area of the education system.

Some of the individual societies have undergone formal changes with regard to name and status. These changes have been connected with definitions of content and range of the discipline within the whole of educational sciences and in relation to neighbouring social sciences to be exemplified by the British and German groupings. Finally, mention should be made about the parallel membership shared by CESE and their individual European counterparts in the *World Council of Comparative Education Societies*. It should be added that this 'duplication' has not affected any conflicts, but, instead, rather strengthened the 'European' position in this world organisation.

Shifts of Theory Paradigm

When looking back to one hundred years of 'true' comparative education in Europe, the observer gets aware of *changes of theory paradigm* referring to

- Key concepts of analysing and interpreting facts and developments in educational reality and discussion
- Impacts on the discipline from neighbouring sciences and humanities

Moreover, these paradigms mirror specific interrelations between socio-political trends and research priorities. Yet, the various historical overlaps and intersystemic references underline the complexity of such changes with regard to the dominance of discontinuity and continuity throughout the single periods, let alone 'survivals' of paradigms which had been considered to have already become obsolete. Concerning the centres of the paradigms, the 'European map' calls our attention to certain local, i.e. university-bound focuses, some of them materialising in 'schools', when specific individual constellations in the form of university chairs or directorates of research institutes are given. Consequently, in most cases such 'schools' have existed as individual centres within a national environment of different academic structure and orientation, and they haven often ended with the departure of the leading figure (chair holder, director, chief of department, etc.). The two following examples are suited to illustrate such shifts. First, the continuous theoretical dedication of the Department of Comparative Education at the University of London could be called 'culturalist', with Nicholas Hans, Joseph Lauwerys and Janusz Tomiak as renowned representatives and reinforced by Edmund King who taught at King's College. However, between the

1960s and the 1980s this focus was challenged by Brian Holmes' concern for positivistic theory and methodology (Holmes, 1965; Holmes, 1981). The Ruhr University at Bochum, to mention the second example, was developed as a centre of Soviet (Russian) and East European Studies by Oskar Anweiler and his associates between the 1960s and the 1980s too. This dedication was not continued by Christel Adick, his successor, who turned to concentrating on the impacts of globalisation and the world system theory on comparative education. As regards the current period, the Humboldt University of Berlin has signalled a new departure, since Jürgen Schriewer's concept of comparative education is distinctly related to the world as a whole, and of applying and modifying the Stanford variant of the world system theory as well as Niklas Luhmann's system theory (Schriewer, 1987; Schriewer, 1999). On the other hand his concept demonstrates that it would be erroneous to regard such 'national schools' as exclusive centres.

On the whole, throughout the twentieth century the trend toward transnational commonalities has never been abandoned. Furthermore, the history of comparative education gives evidence of 'transcontinental' initiatives. In this respect the 'European' influence on the growth of the discipline in the United States before and after World War II is worth mentioning. It is closely associated with the works by the prominent 'emigrants', such as Isaac Kandell, Robert Ulich, George Z. F. Bereday, Harold Noah, Max Eckstein, Andreas Kazamias and Hans Weiler. In the development of comparative education this wave of migration has, in turn, proved to promote transcontinental co-operation in the form of various approaches to reconsidering theoretical and methodological topics. In this context the *Commission* dealing with the observation and development of *theory shifts* within the World Congresses of Comparative Education Societies is worth particular attention. It was initiated by Brian Holmes at the beginning of the 1990s and has been essentially advanced by Robert Cowen and Jürgen Schriewer on the 'European' and by Erwin Epstein and Anthony Welch on the 'overseas' side. Finally, teaching and doing research on both sides of the Atlantic Ocean can be recognised as a reinforcing factor of such co-operation, to be exemplified by Andreas Kazamias' long-year professorships in Madison (USA) and Athens (Greece).

Overall, this analysis of theory positions – offered above – permits the following attempt to structure the twentieth century into a number of periods:

- The decades between the 1920s and the 1950s were characterised by the overarching panoramas composed by Nicholas Hans in England and Friedrich Schneider in Germany, the latter being distinctly influenced by traditional Roman Catholic thinking. They reveal their authors' profound insight into the universal and, in particular, European dimension of educational history and its *driving forces*. Parallel approaches, though after World War II, could be observed in Italy (Flores d'Arcais) and Spain (Juan Tusquets).
- The decades between the 1960s and the 1980s were dominated by the cross-national impacts of the *Positivist dispute in German Sociology* between the adherents of Karl Popper and Jürgen Habermas on content and methodology of comparative education. Besides, neo-Marxist arguments (in various configurations) completed the spectrum.

- The recent period can hardly be ascribed to certain dominating streams, but is rather characterised by competition between converging and diverging theoretical approaches under the universal tension between modernism and post-modernism on the one hand and between universalism (as represented by the world system theory) and cultural pluralism on the other. Besides, the diversified picture gives ample insight into 'new' comparative research areas, such as gender studies, educational planning and politics, lifelong learning, vocational education and, ultimately, the booming field of intercultural education to be resumed in the concluding chapter.

The European mainstream in comparative education has been dominated by 'culturalist' studies until the end of the twentieth century, regardless of its ties to the inherited humanities (*Geisteswissenschaften*) or the advancing social studies. This dominant feature has been complemented by the affiliation with historical studies, beginning with the aforementioned 'grand panoramas' to be exemplified by Nicholas Hans' following comment: 'The first step is to study each national system in its historical setting, and its close connection with the development of national character and culture' (Hans, 1949). The 'contemporary heritage' of that dedication, though rooted in different theoretical roots, is represented by Robert Cowen, Andreas Kazamias, Antonio Nóvoa and Jürgen Schriewer. In contrast to the long-existing and growing trend in the United States, empirical inquiries, in particular those conducted with quantitative methods, remained in the shadow until the last third of the twentieth century. The gap between 'culturalists' and 'empiricists' was even deepened by the independent start of IEA under Torsten Husén's and T. Neville Postlethwaite's leadership which took place in, if at all, only loose connection with the 'established' comparative education centres and associations.

Comparisons in Space

Space has always played an essential role in comparative education (cf. Cowen, 1998). Throughout the twentieth century most studies were based upon the principle of the *nation state* according to the concept represented by Marc-Antoine Jullien de Paris as well as by Michael Sadler. That means that, outside the 'pure' theory-bound analyses, the nation state was defined as the dominant, in fact, almost exclusive subject of comparison. Nevertheless the bibliography of the discipline abounds in comprehensive and detailed studies devoted to the description or analysis of *one 'foreign' national education system*. Studies dealing with the comprehension of two or even several national education systems remained to be exceptional until the last decades of the twentieth century. This apparent deficit was, however, qualified by the 'comparative view' inherent in many 'country studies'.

Responding to trends on the macro-level of educational policies, the nation-related range was widened into regional comparisons in the following three exemplary directions:

First, comparative educationists were motivated to establish 'new' institutions and to initiate research projects by the expansion of home-based education to colonies and other dependent territories. Their commitment was strongly reinforced by the fact that the discipline attracted educationists who had worked as school inspectors or teachers in those areas and wanted to apply their experience by scientific exploration. It seems to

be evident that Great Britain and France were the countries where this focus of interest has flourished until today, having survived the end of colonialism in the liberated states which have, to a great extent, inherited the structural and curricular features of their former rulers' education systems. However, for comparative education as an academic discipline this expansion has turned out to be ambivalent, insofar as many of the practice-oriented 'newcomers' realised that the 'old' institutes and chairs of the discipline did not satisfy their desires as they hoped. Consequently, at some universities, such as the University of London, new institutes arose with special focus on studies in the education of developing countries and separated from the 'traditional' centres of comparative education. This trend was also taken up in countries without any (immediate) colonial past, but with distinct commitment to the new challenge. For instance, Hermann Röhrs (succeeded by Volker Lenhart) established 'third world'-oriented research, in this case, however, within the institutional and curricular framework of comparative education at the University of Heidelberg.

Second, from the 1950s to the 1980s, comparativists in Western Germany, under the pressure of the near Iron Curtain and the German partition, were greatly occupied with the impacts of the West-East conflict on education. In this orientation, however, the German comparativists were not isolated at all. Among their European colleagues Janusz Tomiak (London) is especially worth mentioning as a 'foreign' paramount example. It should be added that this orientation was underlined by the descent of some of the prominent representatives from Central and Eastern Europe (e.g. Oskar Anweiler, Leonhard Froese, Wolfgang Mitter, Janusz Tomiak). Their studies were related to the context of the ideological, political and administrative frameworks of the education systems concerned. After the collapse of the communist regimes the authors of those studies were surprised (and satisfied) at being told by their colleagues in that region that their comments and conclusions had been considered as important, sometimes even the only available and reliable sources and therefore attentively read.

Third, beside the comparative studies whose range was limited to communist countries the history also records some projects dealing with region-crossing themes including West and East European education systems. In this respect Saul Robinsohn's comprehensive project (conducted with Frank Braun, Detlev Glowka and Helga Thomas) on *School Reform in the Societal Process* (Robinsohn, 1970/75; cf. Glowka/Braun, 1975) could claim the quality of a pioneer achievement. Unlike parallel German projects initiated in Bochum, Frankfurt am Main and Marburg, its theoretical scope was explicitly conceived from a sociological point of view and focused on comparing societal factors with their impacts on the national education systems. At the same time Edmund King conducted his comparative project on *Post-Compulsory Education* in five West European countries with its focal explorations of the effects the new trends in vocational education had on 'young adults', in particular concerning their entrance into the labour market (King *et al.*, 1974).

Policy-Orientation

Joseph Lauwerys expressly perceived similarity of comparative education with navigation, insofar as both are only aimed at providing the navigator or the policy-maker,

respectively with information on alternative strategies without trying to exercise influence on their decision-making (Lauwerys, 1958). Considering the history of the discipline as a whole, his position entirely contradicted Saul Robinsohn's concept of the direct advisory function of his proposals in immediate reference to his aforementioned project of the 'Grand School Reform' in Germany at the beginning of the 1970s. While these two radical views can be recognised as the poles of a wide range, the middle is occupied by moderate positions. These definitely accept the melioristic function of the discipline and are ready to provide information for political consideration by suggesting alternative solutions with predictable consequences, but refrain from directly influencing decision-making. As 'indirect' influence is concerned, the judgement is, of course, more difficult, due to the 'informal' channels characterising interrelations among researchers and policy-makers (Husén & Kogan, 1984). In contrast to the situation in other countries including Great Britain, the majority of comparativists in Western Germany were rather reserved to engaging in direct policy consultation and therefore came nearer Lauwerys' than Robinsohn's standpoint, which can be called paradoxical with regard to the tense political situation in the divided country. This estimation is legitimate even with respect to an apparently policy-oriented project like *Vergleich von Bildung und Erziehung in der Bundesrepublik Deutschland und in der Deutschen Demokratischen Republik* which was conducted under Oskar Anweiler's leadership and finalised just immediately before the collapse of the GDR (Anweiler, 1990).

It seems that in the current period the scenario indicates a fundamental shift. This has been caused by the apparently triumphal progression of the international large-scale assessments achieved by IEA and, much more directly, by PISA. Their spectacular success among policy-makers and the public has been considerably caused by the growing position of an economy-oriented educational policy, as strongly promoted by OECD. Comparative education is entirely involved in this process, the more so as in most countries direct intervention of governmental agencies not only on contents and finance, but also on objectives of research projects is increasing.

Perspectives

Like all over the world, comparative education in Europe has to cope with new challenges. However, in this region these seem to be exceptionally strong, insofar as they are connected with deep changes, as regards tasks and aims of institutions, professional competencies of the teaching staffs and supervising agencies. Moreover one has to consider that these bodies are indirectly, of not directly, subjected to interventions by external – political and economic – agencies, both at national and international levels, the latter mostly represented by the European Union as well as by OECD and the World Bank. Apart from this framework the perspectives of the discipline are dependent on the overarching trends resulting from the *globalisation* processes, among which the following three seem to be worth emphasising.

First, the thematic area is getting broader and broader in geographical terms. There is a need for comparisons across continents or between comparative subjects on different

continents. It has the positive effect of uniting researchers from different countries and regions in the initiation and conduction of comparative projects and therefore of connecting the insider's expertise with the foreigner's distant view qualified by an attitude of estrangement. On the other hand such co-operation presupposes the mastering of language and competence issues, caused by academic training under different national and cultural conditions. Modern traffic, electronic communication and the worldwide trend toward using the English language in the global science and communication systems are likely to minimise these difficulties, although these should not be underestimated for the foreseeable future. Finally, globalisation stimulates comparison between themes of local (national and regional respectively) range with worldwide trends, underlined by the inclusion of the historical dimension.

Second, the traditional concentration of comparative studies and projects on comparing *national* education systems and issues has got powerful competition by the identification of *cultural* configurations as significant subjects of comparative education. It is true that *culture* and *cultural pluralism* had fascinated the minds of all the aforementioned 'pioneers' of the discipline who were considerably interested in the *philosophical* and *historical* concerns of language, religion and ethnicity on processes of socialisation and education as *driving forces* of humankind. The recent trend, however, reveals new features, insofar as the spokesmen of those educationists who have introduced the term *intercultural* as complementary to *international* or even *comparative*, are mainly committed to policy-oriented goals. They want to pay a contribution to integrating members of multicultural societies, and that within and beyond national borders. At the same time they are directly practice-oriented, insofar as their efforts are aimed at ameliorating schooling and instruction, e.g. by providing curricula and textbooks and other learning aids and by promoting intercultural communication projects (among students, teachers, local communities, etc.). The special priorities of their goals explain their preference for 'independent' institutions and also associations. Recent evidence, however, shows that divergences from comparative education are not irreversible which has become manifest in joint organisational and substantial ventures, such as demonstrated in Germany by the re-association of the 'comparativists' and 'interculturalists' who had separated in the eighties. Anyway, comparative education has to continue to cope with this challenge and to include the *interrelation between nation and culture* in its range of *comparative* research and teaching, the more so as the traditional concept of *nation* is undergoing essential changes as a concomitant and corollary of trans-national and trans-cultural migrations all over the world. Living up to this challenge, comparative education can pay a valuable contribution to analysing the essentials of multicultural societies, while at the same time this task can be estimated as enriching the thematic and theoretical dimension of the discipline.

Third, academic debate and practice reveal the continuity of the fundamental question of how to define comparative education as an educational and social science area of research and reflection. In the present paper mention has been repeatedly made of the 'discipline' which was, however, focused on the aspect of institutionalisation (in form of institutions, departments or chairs) and needs to be clarified in this concluding context. As the position of comparative education in the science system in total is concerned, the 'European map' indicates different manifestations. The 'German' model and

its counterparts in a good part of Europe (in particular in Central and Eastern Europe) has been characterised by the descent of the discipline from the philosophically (and before theologically) based ‘general pedagogy’, although Oskar Anweiler, already in the sixties of the twentieth century – though contested in that period – defined it as a “cross-sectional area” in reference to its historical and sociological neighbours (Anweiler, 1967). In this respect he contributed to laying the ground for opening its borders to interdisciplinarity without, however, abandoning its traditional affiliation to ‘general pedagogy’ as its ‘mother-discipline’. The ‘British model’ had never favoured the construction of a ‘general’ education and rather preferred the institutionalised and structural formation of individual education disciplines, among which comparative education could be placed without any effort to undergo ‘problematic’ debates. This traditional duality seems to become more and more obsolete, because the increasing and worldwide trend toward *interdisciplinary* studies has included comparative education all over Europe (and more-over the whole globe) to a growing extent, and this trend will go on.

Finally, the way ahead signals a revival of the *European dimension* in comparative education. In former decades it had been avowedly favoured by Nicholas Hans, Friedrich Schneider and Bogdan Suchodolski, to remember the *oeuvres* of three grand ‘Europeans’. While their thoughts were rooted in idealistic and historical reflections, the current drive rather indicates pragmatism, centred round the political debates within the European Union and the Council of Europe including the domain of educational politics, as practised, for instance, by Colin Brock and Witold Tulasiewicz (2000). Philosophical and historical essays have given way to comparative re-analysis of political documents and empirical inquiries. This ‘new’ European dimension has also caught wide-spread response among comparative educationists at the recent CESE Conferences, beginning with the sixteenth conference in Copenhagen (1994) and, up to the present, ending with its twenty-second successor in Granada (2006) (Winther-Jensen, 1996; Kazamias & Spillane, 1996).

It is just this recent ‘return to Europe’ which, in interdependence with the three aforementioned trends, has opened the perspectives of comparative education. However, this estimation should not be restricted to its *lights*. The observer should not overlook the *shadows* either which are caused by fears that comparative education might lose its specific contours when realising that ‘everybody compares and claims to be a comparativist’. Such claims often lack the requirements of theoretical and methodical training concerning the particularities of the *comparative* foundations of the discipline including the continuity of the efforts to define its epistemological identity. However, comparative education, looking back to a history covering two centuries – including its preparatory stage throughout the nineteenth century – has coped with various challenges which seems to legitimate the prediction of its further progress. It is underlined by the articulate participation of European comparative educationists in the worldwide thematic and methodological debate.

WORLD-SYSTEMS ANALYSIS AND COMPARATIVE EDUCATION IN THE AGE OF GLOBALIZATION

Robert F. Arnove

This chapter explores the application of world-systems analysis (WSA) to the comparative study of education systems. Two main theoretical approaches to the study of transnational trends in education are identified: namely political realist and neoinstitutionalist.¹ Following a discussion of their intellectual origins and basic assumptions, the chapter turns to an analysis of the articulation of world-systems analysis with the growing body of globalization research. The interactions between global economic and cultural forces and local contexts are illustrated in representative case studies in the field of comparative and international education. Special attention is given to the impact of major international governmental agencies as well as nongovernmental organizations on education policy agencies. Advances in telecommunication technologies, which compress time and space, are then analyzed with regard to how they shape the nature of work and education system responses. A penultimate section contrasts “globalization from above” with “globalization from below,” the cross-national linking of social protest movements aimed at achieving more equitable education systems and just societies. The concluding section summarizes how different approaches to world-systems analysis, within the more general framework of globalization research, can contribute to theory-building and more enlightened educational policy and practice—principal goals of the field of comparative and international education.

Differing Approaches

Two major streams of world-systems analysis (WSA) appeared in the social sciences and history literature in the late 1960s to early 1970s. One was associated with Marxist-based analyses of the workings of the international capitalist system, beginning with the dependency theories of Gunder Frank (1969), Fernando Henrique Cardoso and Ernesto Falleto (1969), and Theotonio Dos Santos (1970a, b) on Latin America, and Walter Rodney (1972, 1974) and Samir Amin (1970, 1973) on Africa, and culminating in the world-systems scholarship of Emanuel Wallerstein (1974, 1980, 1989).² The other stream is associated with what has been called the “world culture” theory and the “neoinstitutionalist” approaches of Stanford sociologist John W. Meyer with his students and colleagues.³ The more consensus-oriented approach of Meyer and associates to the workings of a transnational cultural and social system has focused

on the establishment and expansion of schooling around the world, principally in the post-World War II period, and particularly in relationship to the creation of citizens and modern polities. The more conflict-oriented school of researchers has focused on the economic dimensions of the world capitalist system with little, if any attention, to the cultural and educational dimensions of the system. In his 1980 essay Robert Arnove, a former student of Meyer, urged his colleagues in the field of comparative and international education to take up world-systems analysis as the necessary framework for understanding educational trends around the world, from curriculum reform to the language of instruction, and the outcomes of school expansion (Arnove, 1980).

Institutionalist Perspectives

The world culture and society work of Stanford University professor John W. Meyer and associates began with attempts to explain the determinants of the global expansion of education systems. In his earliest study, Meyer (1971) first examined country indicators of levels of economic growth and per capita expenditures on education, type of political regime, and colonial past among others to explain the conditions under which countries were likely to increase access to education. Although his findings indicated that wealthier countries were more likely to expand education at all levels, with modernization-oriented governments tending to expand secondary education, and mobilization political systems (e.g., socialist countries) giving emphasis to primary and higher education, these national-level variables did not adequately explain why education was expanding everywhere at a rapid rate (Meyer, 1971).

In a significant collective work entitled *National Development and the World-System: Educational, Economic, and Political Change, 1950–1970*, Meyer and Hannan (1979) concluded that school expansion during this period could better be explained as “a function of the available population to be educated and the level of education existing in 1950.” The important point for world-systems analysis, however, was this: “Education everywhere expanded independent of the constraints and stimuli that economic, political, and social structures provided in previous times. This universal increase in education has led us to speculate that the causes of this expansion lie in the characteristics of the contemporary world system, since such characteristics would affect all nations simultaneously. We offer these speculations as directions for future research” (Mayer & Hannan, 1979: 53).

Further research by Boli and Ramirez (1992), for example, postulated that the institutionalization of compulsory schooling around the world in relation to widely prevalent norms and an ideology concerning the nature of societal and personal development can be traced to the Enlightenment project that followed the break-up of Latin Christendom. The glorification of God was replaced by the celebration of the human project which, by the late twentieth century, became identified with economic growth; and a preoccupation with the salvation of the soul evolved into the notion of the development of human potential. Boli and Ramirez maintain that formal systems of education represent, according to a universalistic ideology, not only the means by which nations modernize and prosper economically, but also the surest route to

enhancing the talents of individuals. As a mandatory requirement of all children and youth of certain ages and as an institution that is regulated by the state, schooling also becomes the agency for creating citizens with equal responsibilities and rights.⁴ Their findings, based on an analysis of six cohorts of countries in relationship to the time lapsed between political independence or state formation between 1820 and 1990 and the establishment of compulsory education systems, indicate that “mass schooling has become the norm in every region throughout the world” (Boli & Ramirez, 1992: 37). Moreover, those regions most incorporated into the Western model of society or attempting to resist Western domination in modernizing their countries (e.g., Japan 1872–1886) also tended to establish rule-governed schooling earlier and more extensively (Boli & Ramirez, 1992: 38).

According to the neoinstitutionalist theoretical framework, the constitution of institutions, like schooling, as well as the construction of nation-states with citizens, is based on widely held and deeply ingrained norms and expectations concerning the way the world is and should be ordered. Meyer *et al.* (1997) argue that “Diffuse functional models about [e.g., the importance of formal schooling to economic growth] . . . actors, actions, and presumed causal relations, are centrally constitutive of world culture.” They provide an example that dramatically illustrates the workings of contemporary world society and culture. They hypothesize what would happen if a previously unknown island society had been discovered, one that had been totally isolated from contact with the rest of the world:

Our island society would obviously become a candidate for full membership in the world community of national and individuals. Human rights, state-protected citizen rights, and democratic forms would become natural entitlements. An economy would emerge, defined, and measured in rationalized terms and oriented to growth under state regulations. A formal national polity would be essential, including a constitution, citizenship, laws, educational structures, and open forms of participation and communication (Meyer *et al.*, 1997: 173–74)

The basis for universalistic rights and obligations of individuals and an emphasis on the rational ordering of society derive from the persuasive power of contemporary world culture, rather than the imposition of norms based on unequal relationships between nation-states. Here the institutionalists draw a distinction between themselves and the world-systems perspectives of the “realists” (i.e., Wallerstein, and other conflict theorists): “Prevailing social theories account poorly for these changes [in the hypothetical island]. Given a dynamic sociocultural system, realist models can account for a world of economic and political absorption, inequality, and domination. They do not well explain a world of formally equal, autonomous, and expansive nation-state actors” (Meyer *et al.*, 1997: 174). The institutionalists’ emphasis on culture—something which realists tend to downplay—may account for the extension of citizen rights to women, specifically the franchise in 133 countries from 1890 to 1990 (Ramirez *et al.*, 1997) or to improvements in the status of young people (Stanford Center on Adolescents, 2005), but the achievement of fundamental political and human rights may be as much the result of struggles of dispossessed peoples as it is the outcome of a

benevolent worldwide system of entitlements based on universalistic norms.⁵ Levinson, for example, examines changing notions of adolescence and secondary education in Mexico, not only with regard to external norms but the response of the Mexican state to pressures from the global economy and various political groups that contest governmental education policies they view as eroding the ideology of the 1910 Revolution (Levinson, 1999).

Realist Perspectives

The assumption of the institutionalists of an international system of autonomous nation-states being able to simultaneously achieve comparable levels of development is precisely what dependency and “realist” world-systems theorists challenge. By the late 1960s, Wallerstein, and his associates questioned the basic assumptions of prevalent theories in the social sciences as well as in international aid agencies concerning the causes of underdevelopment throughout Latin America and the Caribbean, Africa, and Asia. It was not lack of capital and expertise that was holding back these countries, but the very unequal relationships that existed between these countries in the “periphery” of the world economy and the “core” industrialized countries of North America and Europe. The longer the contact between the “core” and “periphery” in an unequal exchange of goods, if not exploitive colonialism, the more likely the country or region was to be underdeveloped—classic cases being the impoverished Northeastern Region of Brazil (Frank, 1969; Cardoso & Falleto, 1969), or Haiti, once the richest colony in Latin America and the Caribbean and now the poorest country in the region.

Wallerstein (2000: 3), who had written his dissertation “comparing the Gold Coast (Ghana) and the Ivory Coast in terms of the role voluntary associations played in the rise of the nationalist movements in the two countries,” had spent a decade living in and writing about Africa as a political sociologist. In his quest (Wallerstein, 2000: 1–4) for “an adequate explanation of contemporary reality, so that . . . [he] and others might act upon it,” he eventually came to the conclusion that “all analysis had to be simultaneously historic and systemic. . . .” In adopting this analytical framework, he was attempting to provide more adequate descriptions of the worldwide upheavals that were occurring in the late 1960s, and why they were likely to fail without radical structural change in the world capitalist system.⁶ At the same time, he was endeavoring to reframe the very nature of the social sciences by bridging the gap that existed in the social sciences “between ideographic humanism and nomothetic science” (the divide between human agency in particular contexts and normative laws of society and nature),⁷

By analyzing vast stretches of history and various cycles in the world economy from the emergence of a capitalistic Western Europe between 1450 and 1600 (the “long century”), he was building on and refining “dependency theory,” which some criticize as a stagnant view of relations between the core and the periphery. According to Clayton (2004), Wallerstein added the dynamic of historicity to this analysis as well as the notion of semi-peripheral countries and zones of the world, with some countries rising and falling from their previous positions in the global economy. For these reasons, the

United States, which has been a successful hegemonic world power, is following the pattern of the Dutch and British empires, in losing its exclusive position as “hegemon” to China and possibly India.

While the institutionalists, particularly those associated with Meyer, definitely have an eye on education systems as a fundamental subject of their research on the workings of a global culture and society, Wallerstein’s analysis has been criticized by Sklair (1999) and others for being too economic as well as overly focused on nation-states as the principal actors in the global economy.⁸ Whatever these criticisms, the value of Wallerstein’s approach to the world-system as the unit of analysis for understanding contemporary reality, especially the impact of transnational economic actors on national education systems, was perhaps first brought to the attention of comparative and international education in Arnove’s 1980 essay in the *Comparative Education Review*.

Applying World-Systems Analysis to Comparative Education

Arnove’s essay departed from the more consensual approach of institutionalists by problematizing the workings and outcomes of agencies promoting educational expansion and reform. Earlier essays had given only a brief nod to the fact that the Western model was a creation of “the economic and military success of the Western powers,” (Boli & Ramirez, 1992: 38). There was an initial tendency not to give much attention to the workings of the major technical assistance and financial agencies involved in promoting, and in many cases imposing, education policy agendas. At the same time, insufficient attention was given to historically unequal economic and political relationships between countries based on various forms of direct domination (for example colonialism) or more indirect forms of overbearing influence (sometimes referred to as “neocolonialism”). Enrolment patterns were one thing; but dropout and completion rates, and how unequal social structures determined who would attend the highest and most prestigious levels of schooling related to future income, power, and status also were not analyzed in great depth. Meyer and Hannan (1979), in their introductory chapter to *National Development and the World System*, do briefly mention inequalities between and within countries; and later writings by Meyer, Boli, Thomas, and Ramirez (1997), Boli and Thomas (1997) certainly discuss the workings of United Nations agencies as well as nongovernmental organizations (NGOs) in promoting educational agendas with an emphasis on inclusion and extension of human rights. But, as noted above, the world culture theorists differ markedly from the realists, who emphasize interstate power relations.

Political realists document the systemic ways in which hegemonic powers in core countries extract surplus labour from the coerced or semi-coerced labour of the non-core regions with consequent deleterious consequences for their education systems. Schooling, rather than serving the interests of the majority in the periphery, abets the process of capital accumulation by hegemonic actors. By contrast, Meyer *et al.* (1997: 173) view various models of societal development as being “Carried by rationalized others whose scientific and professional authority often exceeds their power and resources.” For Meyer *et al.*, “world culture celebrates, expands, and standardizes strong but culturally somewhat tamed national actors.”

Favoring the viewpoint of the realists, Arrove (1980, 2003) argued that these international financial and technical assistance agencies—notably the World Bank (WB), the International Monetary Fund (IMF), the United States Agency for International Development (USAID), the Canadian International Development Agency (CIDA), the Japanese International Cooperation Agency (JICA)—the large philanthropic foundations, especially the so-called “progressive ones” (Carnegie, Rockefeller, and Ford), and related research institutions financed by them, as well as lead universities in the North, were promoting policies and relationships that were not beneficial to the recipients of aid and essentially favored dominant groups in the metropolitan centres of the core countries. He concluded his essay by noting how world-systems analysis restored the international dimension to the field of comparative and international education and provided a framework for understanding educational development and reforms—at that time, comprehensive high schools, educational technologies such as television, open universities, and nonformal education. He argued that linking education policy initiatives to the workings of an international economic order helped “explain why expansion and reform, in so many cases, have failed to effect structural change in education or society, and indeed, why externally induced educational innovation may contribute to perpetuation of existing stratification systems within and between countries.” While not discounting the usefulness of institutionalist analyses of the workings of a transnational cultural system, Arrove noted, much in accord with Wallerstein’s call for a more comprehensive social science linking the nomothetic with the ideographic, that “World-systems analysis not only expands macro analyses to take into account the actions of educational agencies in a truly international system, but it enhances our understanding of the sources of change and conflict in the micro system of school and classroom” (Arrove, 1980: 62).

The Challenge of Globalization Theory

Throughout the 1980s, the expanded focus provided by world-systems analysis spawned numerous studies linking macro- and micro-level variables to explain the workings and outcomes of education systems. By the 1990s, these differing schools of world-systems analysis were increasingly eclipsed by the catch-all phrase of “globalization,” the most salient current theme in the field of comparative and international education according to a recent survey by Cook, Hite, and Epstein (2004: 136).⁹ Developments in computerization, telecommunications technologies, and the ways in which work was now organized—from “Fordist” mass production within national boundaries to “Toyotism” just-in-time production distributed across the globe, led many to believe there was a qualitative change in the nature of capitalist accumulation that could not be adequately explained by diverse Marxist interpretations, including Wallerstein’s WSA, or the world culture and polity approach of Meyer and associates.¹⁰

This is a complex and extended debate that transcends the limitations of this chapter. Briefly, however, if there is a qualitative difference between globalization and WSA, it may be attributed to the dramatic compression of time and space (Harvey, 1989), with greatly improved technologies facilitating the flow of information and capital across

national boundaries and bringing the distant and the local into closer relation in ways previously unimagined (Held, 1991; Held, 1999; Giddens, 2003). Others will argue that the expanded scope and intensity of these linkages are but a variation on the evolution of the world capitalist system or a universalistic world culture.¹¹

What is important to note here is that the space-time dimensions of globalization be distinguished from the content of these informational and financial flows. Much of the literature in comparative education on globalization has equated increased interconnectedness with what has been called the “neoliberal” economic and education agendas that have been implemented across the globe. The term neoliberal derives from the neoclassic economic theories expounded by the dominant international institutions shaping national development policies (i.e., the World Bank and the International Monetary Fund). As summarized by Arnove, Franz, Mollis, and Torres (2003: 324), the theories are based on the work of the classic economists Adam Smith and David Ricardo, who believed that the role of the state consisted in establishing the conditions by which the free play of the marketplace, the laws of supply and demand, and free trade based on comparative advantage would inevitably redound to the benefit of all. Government policies based on these notions have led to a drastic reduction in the state’s role in social spending, deregulation of the economy, and liberalization of import policies. The educational counterparts of these policies have included moves to decentralize and privatize public school systems. Also part of this package of education “reforms” is the emphasis on choice, accountability, standards, and testing by which the state’s role is to specify goals and priorities and evaluate whether or not the various subnational administrative units, and even individual schools, achieve the desired results. At the higher education level, there is the “new managerialism” that applies the language and logic of the market place to overseeing the operations and outcomes of academic units (Deem, 2001; Hartley, 2003; Marginson & Mollis, 2001; Arnove, 2005).

In many respects, the abovementioned developments exemplify the standardization of rules and norms, the isomorphism that Meyer and colleagues had predicted in the constitution of national education systems. Divergence also is contained within their predictions based on certain tensions created by the incongruence between universalistic forces and diverse national characteristics.¹²

Illustrative Studies of WSA

The following sections review how the more consensual (institutionalist) and the conflict streams of WSA have merged in part with the more comprehensive, but amorphous, framework of globalization to shape research in the field of comparative and international education.

Clayton (2004) in a noteworthy review, “Competing Conceptions of Globalization,” points out how WSA, with its historical dimensions, may contribute to comparative education research in ways that most globalization research (because of its short-term perspective) cannot. For example, as he notes, “We would ask not only how educational institutions around the world are today mediating and advancing the neoliberal

agenda but how (or if) educational institutions mediated and advanced liberalism in centuries past, and how (or if) these successive clusters or ideologies differ” (Clayton, 2004: 294). According to Clayton, other studies benefiting from a critical, historical, economic perspective would include those on “the emergence of English as the global language, the global standardization of education credentials or knowledge, the loss of identity and so on” (Clayton, 2004: 294).

In a major statement of the value of a world culture and society perspective, Meyer *et al.* (1997) suggest fruitful lines of inquiry. They include studying issues generated by the tension between external pressures to create modern school systems and internal realities that prevent the realization of beneficial reforms at the school and classroom levels; between ideals related to the equitable distribution of school and policies promoted by reactionary governments and dominant groups who might view democratization of education systems and the teaching of democratic ideals as antithetical to social control and regime stability; or, between international models of years of schooling for different levels of an education system (e.g., 6, 3,3 for primary, middle, and secondary as specified by UNESCO) and what is appropriate for a specific country.

Time allocated to different subjects in national curricula has spurred a number of studies—notably Meyer, Kamens, and Benavot (1992) on *School Knowledge for the Masses*—that show both convergence, in amount of time given to science and mathematics instruction as part of the process of becoming a modern polity, as well as different local adaptations to this international trend. Benavot and Resh (2001: 505) have selected the case of Israel to show how convergence in the diffusion of common categories of curricular subjects across the world is paradoxically modified by another strong policy trend to devolve central state authority over education to subnational levels, a policy bolstered by an ideology promoting school autonomy. Moreover, Benevot, and Resh note that their findings of variations in implementing instruction in nationally mandated subjects “suggest that contextual factors like school structure, the socioeconomic background of students, and the successful mobilization of instructional resources affect the construction of school structure” (Benavot & Resh, 2001: 505).

Anderson-Levitt’s (2003) edited collection on *Local Meanings, Global Schooling* problematizes from an anthropological perspective the convergence toward a single schooling model. In her introductory chapter, Anderson-Levitt raises the question “Is there one single global culture of schooling, or many?” Without taking into account local contexts and cultural meanings, it is unlikely that we will be able to explain adequately what content is actually transmitted, and learned. Her 2004 article on “Reading Lessons in Guinea, France, and the United States: Local Meanings or Global Culture?” explores how it is possible that reading instruction is both significantly similar and different across these three societies. Based on case studies of specific classrooms, she reaches the conclusion that a multi-level perspective (a “double vision”) is required to see how both the transnational and national/local are interacting and simultaneously enabling and inhibiting teaching practices: “[T]he double vision of teaching leads to a double vision of educational reform efforts. On the one hand, we cannot expect any top-down reform to produce the same results in different places. On the other hand, local attempts to reform operate within a broad but real framework, the current transnational model of good teaching.” (Anderson-Levitt; 2004).

The importance of taking into account human agency when studying teacher responses to international educational currents is the object of a study by Stacki (1999), on a UNICEF-funded innovative in-service teacher education program in Uttar Pradesh, India.¹³ The case study provides a richly textured, multi-layered account of the history of teacher education reform efforts in India; the role different agencies (international, national, and local) play in formulating and implementing this particular teacher empowerment project; and specifically how two female teachers respond to this professional development program.

How do students and community members respond to “the constraints placed upon their lives by the world system of incommensurate differences and their marginalized place within it”? These are the questions examined in Demerath’s (1999) ethnographic study of Pere Village in Papua, New Guinea.¹⁴ He documents how the subjects of his study negotiate tensions emanating from global and cultural and economic forces that result in a situation of increasing educational credentialism, limited job markets, and threats to traditional community life. In order to cope with dim job prospects, many students reject continuing with their education and even belittle their peers who do. These disenchanted youths glorify village life. Yet, it remains true that higher educational attainment could lead to jobs in the modern sector of the economy as well as access to desirable commodities not available outside urban areas. Villagers themselves are caught in the same dilemmas of choosing between the old and the new (Demerath, 1999: 102).

These studies (Benavot and Resh, Anderson-Levitt, Stacki, and Demerath) examine what Monkman and Baird (2002) have called the “how” of globalization. They give meaning to what otherwise remains an unexplained context or something that happens without understanding the processes at work:

Thus, much of the case study research on globalization focuses on national and local responses to “globalizing” pressures. A useful mapping of the relationships of the local within the global would result in a focus on the nature of national and local involvement or interaction within globalization processes. This conceptualization would more adequately reveal the interpenetration of the global and local and the mediating influence of nation-states and local communities. (Monkman & Baird, 2002: 498)

Monkman and Baird, in addition to calling for multiple-level analyses of the working of global forces on national and local contexts, argue for the value of studying discourse and participation—who is defining globalization in what terms and who is involved in international and national decisions defining educational strategies and policies.

International Institutions and the World-System Revisited

The issues of discourse and participation are addressed in Carnoy and Rhoten’s (2002) guest editorial essay in a special issue of the *Comparative Education Review* on “The

Meanings of Globalization for Educational Change.” They call attention to the “ideological packaging” of globalization and its “effect on the overall delivery of schooling, from transnational paradigms, to national policies, to local policies” (Carnoy & Rhoten, 2002: 2). As they note, this ideological packaging favors an emphasis on the economic goals of an education system—how it contributes to the internationally competitive position of a country—rather than to such important goals as contribution to national cohesion through equal treatment of various ethnic groups in a country.

This ideological agenda, according to Carnoy and Rhoten (2002: 2), is increasingly tied not only to global economic forces, but to “international institutions that promulgate particular strategies for educational change” (a point made earlier by Arnove, 1980). The discourse of these international agencies is tied to cost-benefit and production function analyses of the value of different levels and types of education, an analytical framework that former World Bank education staff member Heyneman (2003) admits has had serious limitations and negative consequences for more equitable and effective education policies¹⁵

The workings and inter-institutional relations of the major international technical assistance and financial agencies is the subject of a growing body of scholarly work by Mundy (1999, 2002) and Jones (1992, 1993). Mundy (1999) for example, traces how UNESCO with its humanistic orientation toward life-long learning systems has lost its position as the leading United Nations agency setting policy directions for education to the more economically minded World Bank (a point reaffirmed by Heyneman, 2003). According to Mundy (1999: 46), UNESCO’s views on education had changed by 1996. An internal report, *Learning, The Treasure*, noted that “technical change and economic globalization were rapidly undermining existing social policies, the structure of work, and global equity in general.” In an earlier article, Mundy (1998) documented how the ideology of multilateralism (institutionalized coordination of relations among three or more states on the basis of generalized principles of conduct)¹⁶ has changed from one of a “limited redistributive” set of values involving education (1945–1965) to a period of contestation, coming especially from the less-developed countries of the South “demanding a social welfare model of national development” (late 1960s to late 1970s) to the current, or ongoing, stage “during which neoliberal defensive and disciplinary forms of educational cooperation emerged” (Mundy, 1998: 476). A consequence of this latest stage furthers the erosion of the redistributive model of educational multilateralism.

The emerging structures of global governance, economically, and educationally, now include major regional organizations like the European Union, the North American Free Trade Association, and the Asia Pacific Economic Cooperation (Dale & Robertson, 2002). In addition to the emergence of these regional organizations, the World Trade Organization has achieved an ascendant position in international commerce in education. The mechanisms and processes by which these organizations shape education systems have been analyzed by Dale and Robertson among others. Dale (1999) specifies eight nontraditional mechanisms and related organizational features that influence the nature of external effects on national policy.¹⁷

In a further effort to open the “black box” of globalization, Robertson, Bonal, and Dale (2002) examine the General Agreement on Trade in Services (GATS). They

provide a conceptual framework and a “rigorous set of analytic categories that might enable us to make sense of the profound changes now characterizing education in the new millennium” (1999: 472). Their model of “pluri-scalar governance of education,” comprehends three dimensions: 1) three scales of governance going from the supranational, to the national, to the subnational; 2) the institutions of governance—the state, market, community, and household; and 3) governance activities consisting of funding, ownership, provision, and regulation (1999: 478). As they note, in 1995, the General Agreement on Trade and Tariffs (GATT) was replaced by the World Trade Organization (WTO). The WTO is now a major, if not the most significant, player in constructing “a hypothetical world education system, free of barriers” that would involve “internationalization of educational credentials or a possible globalization of knowledge production and consumption but also would affect central aspects that largely have been under the control of nation-states. . .” (1999: 489). An important point is that for many countries the WTO is not simply “an instrument of global capital,” but something that a number of nation-states are eager to join “as they seek to advance their own national interests in the global knowledge economy” (1999: 495).

Clayton (1998), in his article “Reconnecting World-System Theory for Comparative Education,” made a similar point about the need to study the various ways in which nation-states respond to globalization and specifically international educational assistance. These responses range from resistance to accommodation by “periphery students, teachers, administrators, and policy makers aware in varying degrees of the implications of their actions” (1998: 496). Clayton argues that these actions are best explained in relation to concepts of hegemony, class relations, and human agency.

An interesting question is how the position of a country in the world economy and its size, resources, and political strategic significance influence how much autonomy it has in responding to the policies and regulations of the World Trade Organization. To what extent is state control over the nationally important and culturally sensitive domain of education compromised by joining the organization? What are the implications for a country like China (Zhou & Shi, 2003) as compared with an island-nation like Jamaica or an impoverished country like Nicaragua?

At the same time, another set of actors, namely nongovernmental organizations (NGOs), also erode state control over educational policy and practice.

Ascendancy of NGOs as International Actors

As Mundy and Murphy (2001) and others have pointed out, international financial and technical assistance agencies are increasingly working with nongovernmental organizations, many of whom are international in reach, to provide educational services once the exclusive domain of the state.¹⁸ NGOs have become major transnational advocates for the universal extension of education as a human right. In many cases, binational, and multilateral donors consider it preferable to work with NGOs rather than government bureaucracies that are considered to be corrupt and/or inefficient. This preference raises a number of major issues explored by Sutton and Arnove (2004) in their edited volume *Civil Society or Shadow State? State/Ngo Relations in Education*. The set of

case studies ranging from Papua New Guinea to Peru examine these questions: As educational services providers and innovators, do NGOs relieve the burden on the state of providing universal basic education as well as adult education and literacy programs? Conversely, do they erode the legitimacy of the state as the primary entity that establishes the goals, content, credentials, and materials of public schooling while also regulating key features of the system's administration and financing? Do the NGOs, themselves, lose their legitimacy, moral authority, flexibility, and sensitivity to local needs, as well as their roles as advocates on behalf of grassroots initiatives as they serve as contractors for national governments or international and binational donor agencies? Moreover, as a consequence of their close relationship with these agencies, are they more likely to manifest the possible negative features associated with them like partisanship, cronyism, and corruption (Sutton & Arrove, 2004: x; Kamat, 2004)?

Illustrative of these questions is the case study by Christina (2001, 2006) which examines government-NGO relationships in the formulation and implementation of early childhood education in the West Bank. This study places the Palestinian case in historical and comparative context, illustrating the relations between global social forces and local cultural and political contexts. The study compares the differing visions and policy orientations of a model NGO with those of the Palestinian National Authority and international donor agencies. A wealth of data details the struggles of the principal actors in the early childhood program to remain sensitive to their goals of honoring indigenous culture while retaining their ideals of a child-centered, progressive education corresponding to international norms.

Ether Space and the Flow of Information

In addition to the traffic in aid, trade, and services across national borders, there is the flow of information. Instantaneous access to information is an integral component of the "new knowledge economy" (Castells, 2004; Carnoy, 2000). Telecommunication technologies have led to changes not only in the organization of work in the production of material goods but to how services like education are delivered. The impact of these technologies is particularly notable at the higher education level, where courses and, in some cases, entire academic programs are offered on-line and various partnerships or "franchising agreements" are forged between universities in the metropolitan centres of North America and Europe and the rest of the world. Problematic issues in these arrangements concern the language of instruction and the appropriateness of curricula.¹⁹ The most extreme form is a "virtual university." They raise questions concerning who "attends" such institutions and what the outcomes are for these students in relation to those who study in more traditional universities. Do universities, for example, lose their role in contributing to national culture or being centres of critique, if not opposition, to corrupt and repressive governments? Are public schools no longer the primary state-controlled locus for creating a collective identity and preparing citizens?²⁰

These issues are raised in the book by Edwards and Usher (2000) on *Globalization and Pedagogy: Space, Place and Identity*. New information and communications

technologies create a “‘diaspora space’ in which individuals can liberate themselves from the limitations of established norms and create their own hybrid identities” (as summarized by Monkman & Baird, 2000: 501). The upside of this “ether space” is that individuals and their social groupings can now connect across national boundaries to those sharing similar interests or learn about those who otherwise would be a distant and unknown “other.” The educational potential for creating more globally minded and multiculturally sensitive individuals is enormous. Teachers as well as students, at all age levels, can communicate with one another to share their everyday concerns and aspirations for a better world.

Politically, transnational movements for social justice are able to reinforce one another and call on the international community to support their struggles. This has happened with various movements—feminist, ecological, ethnic minority, trade union, and refugee among many—as they demand fundamental human rights for their members, one of which is a right to a quality education. Education and the rights of indigenous groups, for example, is a current topic of interest in comparative education (see the special issue of *Comparative Education* (2003) as are themes pertaining to the citizenship status of immigrant and refugee groups.²¹ Just as there is globalization from above, there is globalization from below (Brecher *et al.*, 2000).

Globalization from Below

Arnové (2005) has taken this notion to provide a framework for studying the locus of educational reform initiatives (a vertical axis indicating whether they are top-down or bottom-up) and their goals (a horizontal axis indicating whether they are primarily economic or political-cultural).²² A review of recent dominant policies—privatization, decentralization, choice schemes, and various accountability measures based on standardized testing—finds that they are largely initiated at the top in international and national bureaucracies, and that they are oriented, as previously discussed, toward economic goals. At the same time there are, as just mentioned, a growing number of grassroots initiatives aimed at the achievement of more equitable societies and education systems that are closely related to cultural identity movements.

How do these various initiatives relate to world-systems analysis? As is evident in the literature review, the programs initiated from above are integrally related to changes in the dynamics of the global economy, the demands for a different type of work force based on certain skills and knowledge. The new information age economy is one in which many individuals will be displaced and the rights of organized labor will be threatened by transnational corporations. These corporations seek out countries, and regions within them, where the greatest profits can be obtained for differing reasons—in many cases because labor is cheaper and more exploitable (Mexico, Indonesia, Guam, Vietnam), or because it is both cheaper and skilled (e.g., Bangalore, India) or, for all three reasons (China). As described, these trends reflect the predictions of world-systems analysis as formulated by Wallerstein and his associates. The disruptions caused by changes in the way capital is accumulated also help explain the phenomena of social protest movements from below. At the same time, these movements are inspired by the

widely circulating ideals of human, civil, and political rights as explained by the writings of “world culture” neoinstitutionalists Meyer and associates.

The disruptions, manifestations of what Wallerstein (1997: 6) has called the “terminal crisis” in the historical system in which we live, present the opportunity for moving world-systems analysis to a more centrally prominent position in the social sciences and “formulating the central questions of the enterprise.” (Wallerstein, 1997: 6) Among these questions for the social sciences are: “What are the processes of transition from one historical system to another?” And “What is the theoretical relation between the quest for truth and the quest for a just society.” For Chase-Dunn (1999: 16), the current disruptions and crises represent an opportunity for diverse progressive movements to unite to bring about “global social democracy.”

Conclusion

The diffuse phenomenon of globalization has reinforced the importance of world-systems analysis, whether of the consensus or conflict type, for the field of comparative education. One could say that the two streams of world-systems analysis have entered the ocean of globalization research. This confluence of systematically evolving intellectual currents has been beneficial. It has stimulated further inquiry to refine and elaborate the theories and methodologies that will enable scholars, policy makers, and practitioners to better understand the multidimensional, transnational trends shaping the workings and outcomes of education systems everywhere. Understanding the world is a key to changing it for the better—a goal much in accord with scholarship in the field of comparative education and its missions of contributing to theory building, more enlightened educational policy and practice, and ultimately to international understanding and peace.

Notes

1. Paulston (1977) and Ginsburg *et al.* (1990) have referred to these major theoretical approaches as “equilibrium” and “conflict,” while Hurn (1993) uses the terms “consensus” and “conflict” to describe two major paradigms for studying education and society. This author prefers Hurn’s terms and will occasionally use them to describe the institutionalist and realist approaches to world-systems analysis.
2. Wallerstein, it should be noted, is indebted to the French school of socioeconomic historians associated with the journal *Annales d’Histoire Economique et Sociale* and especially Fernando Braudel whose “long view” of historic formations and attention to minute detail is best illustrated by his magisterial three-volume *Civilization and Capitalism, 15th–18th Centuries* (1981).
3. Wikipedia encyclopedia (2005) defines the “New Institutionalism” as “a social theory that focuses on developing a sociological view of institutions, the way they interact and the effects of institutions on society. It is significant in that it provides a way of viewing institutions outside of the traditional views of economics. . . .” Bruce Fuller (2004: 328) elaborates on this definition: “Old institutional theory, advanced by sociologists such as Arthur Stinchcombe and Jerald Hage, argued that formal organizations work from articulated goals and specified technologies and eagerly attempt to deliver on their promises. . . . Instead, the neoinstitutionalists emphasize that nations must make sense of their membership in a global social arrangement not always defined by their position in the world economy.” For purposes of this essay, however, I have decided to use the term “institutionalist” perspectives.

4. For further discussion of this point, see Bendix (1996).
5. See, for example, Zinn (2003), esp. pp. 683–688.
6. From an autobiographical statement by Wallerstein (2000). Also see Chase-Dunn (1999) and Chase-Dunn & Boswell (2000).
7. Wallerstein (1997, p. 4) is careful to note that “world-systems analysis is not a theory but a protest against neglected issues and deceptive epistemologies.” He continues, “It is a call for intellectual change, indeed for ‘unthinking’ the premises of nineteenth-century social science.... It is an intellectual task that has to be a political task as well, because – I insist – the search for the true and the search for the good is but a single quest.”
8. Clayton (2004), however, believes this criticism isn’t accurate as Wallerstein sees a decoupling between the economic and political spheres of the global system with the nation-state being but one component of various political formations working in conjunction with and sometimes in opposition to the world capitalist economy. Also see Chase-Dunn (2000) on this disconnect.
9. Among the books in the field of comparative education taking globalization as a major organizing theme are Arnove & Torres (1999, 2003), Burbules & Torres (2000), Stromquist & Monkman (2000), Suárez-Orozco & Qin-Hilliard (2004).
10. For further discussion of qualitatively different aspects of globalization, as compared with WSA, see McMichael (2000) and Martin (2000).
11. For further discussion, see Clayton (2004).
12. The importance of the local is the focus of Deem’s (2001) study of the “new managerialism” in higher education.
13. The study won the Comparative and International Education Society (CIES) Gail P. Kelly outstanding dissertation award in 1999. A summary of the case study is found in Stacki (2004).
14. The study, based on his dissertation research, won the George Bereday Award for the best article in the *Comparative Education Review* in 1999. A noteworthy feature of Demerath’s research is its illustration of the limitations of “rational choice theory” and “cost-benefit” analyses of education, as well as the social utility of certain courses of action, when specific sociocultural contexts are not taken into account.
15. For further discussion of World Bank policies and their consequences, see King (2002), Soudien (2002), Moura Castro (2002), King (2002), and Bonal (2004).
16. For further discussion, see Ruggie (1992, p. 571).
17. Two of the categories involve “borrowing” and “learning.” For the difference between these two and their significance for comparative education, see Phillips and Ochs (2003). Also pertinent to the literature on “borrowing” and “lending” in education is the edited collection by Steiner-Khamsi (2004).
18. Boli and Thomas (1997), for example discuss NGOs as major constitutive elements of an emerging “world polity.”
19. For a more general discussion of issues and challenges facing higher education institutions in the age of globalization, see Altbach, Bloom, Hopper, Psacharopoulos, and Rosovsky (2004), and Marginson & Mollis (2001), esp. pp. 599–600.
20. With regard to challenges to the state from globalization as well as issues concerning theoretical frameworks for studying international education trends, see Welch (2001).
21. A different theoretical lens for viewing the ways in which different groups coalesce around common concerns is provided by International Regimes Theory. For an application of this theory to studying how an indigenous group in Colombia is resisting encroachment of foreign oil corporations on their territory, see Wirpsa (2004). Also relevant to this discussion is Relational Theory, the subject of the 2000 CIES Presidential Address by Ross. The role of education systems in preparing marginalized groups for democratic citizenship is a subject of the co-edited volume by Stevick and Levinson (2006).
22. This framework is based on one initially proposed by Paulston and Leroy (1980) to study nonformal education programs.

REFLECTIONS ON THE DEVELOPMENT OF COMPARATIVE EDUCATION

Val D. Rust, Brian Johnstone, and Carine Allaf

This chapter deals with our reflections on the development of the field of comparative education. We ask three major questions. What are its beginnings? Where has it gone? Where is it going?

The Beginnings of Comparative Education

Beginnings are often vague, ill-defined, and tangled. Accounts of a beginning are often best associated with the mind of the storyteller than the thing itself, and so it is with reports of the beginning of comparative education. Some people are satisfied with vague generalities. And so, comparative education began during a shadowy time in antiquity, when descriptive tales of “useful lessons from foreign practices” were brought home by travellers to foreign parts, by “amateurs,” who happened to take note of an exotic educational situation or school in another culture (Noah & Eckstein, 1969). It is believed to have begun in the West when classical Greeks such as Pindar, Herodotus, Xenophon, Cicero, and Julius Caesar described educators and education in lands beyond their own borders (Fraser & Brickman, 1968).

In this context, the origins of comparative education are “ancient” and associated more with an art, in that those practicing it were concerned with the practice of learning and teaching (Hilker, 1962). Stewart E. Fraser and William W. Brickman remind us of a “growing awareness of the monumental comparative writings of previous centuries” related to comparative and international education (Brickman & Fraser, 1968). One task comparative educators have is to catalogue these writings in some systematic form.

Even the origins of the term “comparative education” are a bit muddled. As early as 1785, Thomas Jefferson made reference to “comparative advantages of an American rather than a European Education” (Jefferson, 1785), but the actual term was likely first used by William Russell in 1826, in his translation of Marc-Antoine Jullien’s questions on *l’éducation comparée*, written in 1816–1817. Thus, Jullien may have been the first to use the term, at least in the French language. In 1888–1889, William T. Harris made reference to “a science of comparative pedagogy,” suggesting that the term “comparative education” had not been universally accepted in Americans by that time (Harris, 1889). The Germans continue to debate whether the term should

be *Vergleichende Erziehungswissenschaft* (comparative educational sciences) or *Vegleichende Pädagogik* (comparative pedagogy) (Hilker, 1962; Schneider, 1961).

In 1816–1817 Marc-Antoine Jullien began perhaps the first documented initiative in the field of comparative education. He recommended that nation-states collect data and catalogue educational conditions through questionnaires he would design that would be reviewed by a special committee, composed of experts from various countries. This information would then be shared by countries and serve as a frame of reference for formulating educational reform policy in various countries (Fraser, 1964).

Comparative Education and the Academy

For most scholars, comparative education began when it became recognized in the modern academy, with its growing orientation toward specialization and scientific investigation. Comparative education did not appear as a subfield of education until educational studies were adopted by teacher training institutions and universities.¹ With university programs in education came appointments of faculty devoted to comparative education, courses in comparative education, textbooks for comparative education students, and academic journals that published research findings and self-reflections on the field. Thus, comparative education is popularly believed to have begun in 1899, when Teachers College, Columbia University in the United States developed the first course in comparative education one year after Teachers College became a part of Columbia University (Bereday, 1963). Curiously, George Bereday, who had already published James Russell's syllabus of the 1899 course, stated that the tradition of comparative and international studies at Teachers College dates back to World War I, with the publication of the first textbook in comparative education by Peter Sandiford (1918). That textbook, of course, was titled *Comparative Education* (Bereday, 1960). As was the case with Sandiford's edited volume, almost all of these early textbooks introduced university students to comparative education as the notion of "education in" this or that country or world region (Bereday, 1963).

The first journal devoted to comparative education was begun by Friedrich Schneider, a professor at Köln University in Germany, who in 1931 established the *Internationale Zeitschrift für Erziehungswissenschaft* (*International Review of Educational Sciences*). In the first edition, Schneider outlined what he felt was the history, system, method, purposes, and contributions of comparative education, and he attempted to establish a terminological base from which the discipline would function (Schneider, 1931/32).

Some scholars set the beginning of the field with the formal establishment of professional associations dedicated to comparative education. The first such organization was initially named the Comparative Education Society, and its constitution was ratified in 1956, though its name would later be changed to its current title, Comparative and International Education Society (CIES). In that same year, a formal journal, the *Comparative Education Review*, was established by CIES, intending to provide an outlet to scholars of research and reviews of works appearing in the field.

The senior author of this essay, Val Rust, had a personal experience with beginnings, related to doctoral students in the field, who would be expected to take over university

appointments as specialists in comparative education. Even though university appointments had been made prior to doctoral programs in the field, these appointments consisted of people who had been trained in fields other than comparative education. The foundations of the field of comparative education were established by scholars representing historical and humanistic inclinations, including historians Isaac Kandel, Friedrich Schneider, Nicholas Hans, Robert Ulich, Andreas Kazamias, Claude A. Eggertsen, and William Brickman, and scholars who rely on what Robert Cowen calls “the culturalist motif,” such as Joseph Lauwerys, W. D. Halls, Vernon Mallinson, and Edmund King. Of course, there were good early comparative education scholars whom we identify with the more conventional disciplines within the social sciences, including C. Arnold Anderson in sociology, Philip Foster, and Harold Noah in economics. Interestingly, Max Eckstein is so closely identified with Harold Noah that his name is usually connected with Noah’s orientation, although Eckstein comes from a literature and humanities background.

Val D. Rust’s own doctoral advisor, Claude A. Eggertsen, mentioned above, was born in a little railroad junction in Utah known as Thistle in Spanish Fork Canyon. At Thistle, his father was a railroad man, but he saw to it that Claude had the preparation necessary to go to College at Brigham Young University where he studied history, then to Stanford University, then the University of Minnesota, and finally he moved to the University of Michigan where he established himself as a prominent historian of American education. World War II had a profound impact on his life and upon returning to his office in Ann Arbor, he felt cramped by his field of research: it was too small, too confined, too limited. He embarked on the field of comparative education, transforming himself from a student of America to a student of the world (Rust, 1987).

Influences Across Cultures

It is unfortunate that many of those explaining early academic comparative educationists have been so locked into a certain view of scholarship that they have tended to discount early versions of the field or cast them as inferior and defective. It has been difficult for them to recognize that even “amateur” traveller’s tales had their virtues and value. Academic comparative educators have tended to judge so much of the nineteenth-century comparative education studies as inferior in that it was “utilitarian” filled with “description,” “without reasoned analysis” and “eulogistic” (Templeton, 1954). These academic assessments were quite accurate about the nature of these comparative works. They were indeed utilitarian, practical, and oriented toward the general improvement of schools and educational systems. But the studies have been harshly judged because they reflected a type of comparative study that is not common in the field today. That is, they focused on what might today be referred to as “influences across cultures.” In fact, there are contemporary academic fields of study, including comparative literature, that rely almost exclusively on this type of activity. Comparative literature scholars are certainly humanities oriented, but their basic quest has strong science overtones in that they attempt to unravel interrelationships between individuals, schools of thought, or national literatures across time and space.

In terms of time, comparative literature specialists wish to chart how German Catholic literature influenced German classicism and how it, in turn, influenced romanticism; how Shakespeare changed English literature; and how modern European literature is in debt to Greek and Latin literature. In terms of space, the comparative literature scholar wishes to trace the movement of themes and genres from place to place: how religious themes in Switzerland migrated to the Netherlands, then to America; how Tolstoi, Emerson, and Thoreau influenced Indian writers in South Asia; how Africa incorporates European writing styles; how the Don Juan archetype moves from culture to culture (Highet, 1992; Weisbuch, 1989).

Just as in the field of comparative literature, “influences across cultures” is a definite and wonderful part of the comparative education heritage that ought to be more highly prized and appreciated than it sometimes is. Comparative education specialists could make a great contribution to the field’s work by paying attention to historical and contemporary endeavors. The work of countries such as Norway, in terms of national reform policy formation, has been especially significant. In the Norwegian educational reform tradition, for example, a commission has usually been established either by Parliament or a Department of the government to study the situation and make recommendations for change. Their recommendations have come in the form of white papers, and, from their inception in the 1840s, these commissions have always described relevant conditions in all Scandinavian countries, the rest of Western Europe and even North America that served as options for consideration of alternative courses of action and models for potential adoption (Rust, 1990). By exploring the “external” educational world, Norway was able to make appropriate and useful improvements to their own educational system.

Just as Norway looked to other European countries, the United States also took a vested interest in Europe, developing relationships with France, Germany, and England. The American involvement in Prussia was part of a general swell of interest throughout Europe in the 1830s and 1940s initiated mainly through the report of a French scholar, Victor Cousin, who had been sent to Germany by the French Ministry of Education in 1831. Sarah Austin’s English translation in London of Cousin’s report in 1834 found its way to the United States and served as a trumpet-call for a general exodus of educators and statesmen from the United States to Europe, in particular to Prussia. Indeed, Burke A. Hinsdale eventually came to write that Cousin’s report “produced results, direct and indirect, that far surpass in importance the results produced by any other educational volume in the whole history of the country” (Hinsdale, 1906).

Of course it was utilitarian, descriptive, and eulogistic. Following a trip to Europe, Calvin E. Stowe returned to America to declare before the Ohio legislature that the Prussian educational system was no “visionary scheme,” but represented a program of instruction “in the best school districts that have ever been organized” (Stowe, 1930). Alexander Dallas Bache returned to America from a 2-year study of European schools to report that Prussian primary education was the “most perfect of the centralized systems” (Bache, 1839). Horace Mann, Secretary of the Board of Education of the State of Massachusetts from 1837–1848, stated in his Seventh Annual Report: “Among the nations of Europe, Prussia has long enjoyed the most distinguished reputation for excellence of its schools” (Mann, 1844). The same praise was expressed by the

Superintendent of Common Schools in Connecticut, Henry Barnard, who claimed that the Prussian schools had “attained a degree of excellence, which has attracted attention of statesmen and commanded the admiration of intelligent educators in every part of Christendom” (Barnard, 1854).

Comparative educator Isaac Kandel would certainly have condemned such accounts of Prussian education because he felt they were permeated with “mere descriptions of administration, organization, and practices . . . written wholly from the point of view of education alone, without any closely reasoned analysis of what the systems stood for or represented in the field of national progress and development . . . ; they were in general not prepared in the light of their bearing on specific American problems, or, if they were prepared with this end in view, sufficient allowances were not made for differences in national environments” (Kandel, 1930).

Such condemnations, including that of Kandel, took these reports out of context and discounted the acute awareness American educational specialists had of the situation in Prussia. The recommendations of the American reports were not universally accepted by American policy makers, who opposed adoption of the Prussian schools, because the schools were seen to be used by the Prussian state to perpetuate monarchical aims and to check the growing revolutionary spirit within the boundaries of that Prussian state. In response to this challenge, the reformers quickly admitted there was a relationship between Prussian schools and despotism. Calvin E. Stowe openly conceded that the whole educational program of Prussia was “to unite with the military force which always attends despotism, a strong moral power over the understanding and affections of the people” (Stowe, 1930). However, the American reformers countered this negative argument by stating that the evils were naturally separable from the good. Horace Mann maintained that if the Prussian schoolmaster could teach reading, writing, geography, and arithmetic in half the time that was required in America, then surely they could “copy his modes of teaching these elements, without adopting his notions of passive obedience to government” (Mann, 1844). He argued that human faculties were the same everywhere. The best means for their growth and development would therefore also be the same, and good schools can be used to strengthen the democratic and republican spirit in America. Certainly, context and analysis mattered to the American school reformers who were engaged in comparative education study.

Comparative educators have been sensitive to foreign influences on education; as comparative education became an academic field, its founders were generally more sensitive about the possibilities of drawing on foreign models with the purpose of “perfecting national systems with modifications and changes” than of including past influences from abroad in their own analyses of a nation’s educational system (Hans, 1955). Clearly, early comparative studies were intended to make a direct contribution to the American common school movement that led to the establishment of an American school system. Consequently, the American common school was almost an exact copy of the Prussian *Volksschule*. Curiously, these American reformers often retained the French terms used by Cousin. Consequently, the American normal school is a replica of the German teacher training seminar, though the term we use is French.

Fortunately, these types of early, pre-academic comparative education activities have not disappeared from our current academic activities. Some important work

has been done in comparative education circles related to tracing influences in educational change and reform. Harry Armytage, for example, has written four books tracing the influence of America, France, Germany, and Russia on English education (Armytage, 1967, 1968, 1969a, b). Friedrich Schneider devoted most of his period of exile from Nazi Germany tracing the influences of German education on other countries (Schneider, 1943). Even though his choice of topics is understandable, given the National Socialist context within which he was working, his contribution to “influences” remains significant. Some of the work of the senior author of this essay has focused on the reciprocal influences on education between Germans and Americans (Rust, 1967, 1968, 1997). In fact, Rust’s own dissertation represents one of the few studies of a single country’s historical interest in education beyond the borders of that country (Rust, 1967).

Fortunately for specialists in comparative education, significant contemporary work is being engaged in relation to “influences across cultures” at least in borrowing terms. Recently, scholars at Oxford University, under the leadership of David Phillips have engaged in a process of conceptualizing what goes on in the “borrowing” process between nations, particularly as they relate to policy formation and implementation (Phillips & Ochs, 2003). The Oxford framework is not dissimilar to that developed by Rust in his study of educational policy formation and the implementation process in Norway, which involve a series of phases: initiation study, consensus-building, legal framework, and implementation (Rust, 1989).

Phillips and his colleagues have engaged in a large number of case studies, both geographically and historically that demonstrate part or all of the borrowing process (Phillips, 2004). These Oxford scholars have been joined by people such as Gita Steiner-Khamsi at Teachers College, Columbia University, who is concerned not only with the borrowing process but also the lending process (Steiner-Khamsi, 2004).

The borrowing process has gone on as long as there have been separate administrative units that have maintained relations with each other. It is not clear how globalization provides special contextual and circumstantial issues to be dealt with. Most of the borrowing that has been documented has been between nation-states or between systems of education in the modern age. With the emergence of transnational conditions within the context of globalization, new models are yet to be developed that illuminate the borrowing and lending process in education, as will be discussed in the final section of this essay.

Comparative Education as a Scientific Enterprise

If there is a common theme that runs through the history of comparative education, at least as an academic field, it is its quest to be a science. Such a quest is also reflected in the whole field of educational studies. In 1887, the first American professor of education, William H. Payne, posed the specific nature of the issue, by noting “education is chiefly an empirical art.” There is “no science of education” but a major purpose of the field in higher education “is the development of educational science” (Payne, 1887). This is not just an American issue. We noted earlier that some Germans have preferred

to use the term comparative pedagogy, because it reflects a middle ground between the idealistic and the realistic, an educating art, an empirical art, the contradictory notion of the “art of science.” Our own position related to comparative education is that it has never been devoid of science impulses. Even the pre-academic practice comparative education, which we refer to as “influences across cultures,” has clear scientific dimensions.

Comparative education must be viewed as one of a number of comparative fields of study that have emerged at the time science was becoming a part of academic studies. Comparative fields of learning were seen to emerge in the life sciences in the seventeenth and eighteenth centuries AD, as subfields of anatomy, paleontology, and embryology, but they quickly expanded to almost every field coming into existence. In fact, some of these fields, including sociology, were initially identified as comparative in nature.² In 1905, Louis Henry Jordan, wrote a large volume entitled *Comparative Religion*, where he extolled no less than 26 comparative fields, claiming that the common property of all these fields was their “distinctive methodology.” That is, they all used the scientific method and aimed “to expound those fundamental laws of relation.” And, according to Jordan, comparative education was one of the more exemplary of these “scientific” comparative fields, because “no method of inquiry has proved more fruitful of wise suggestions.”³

If the example of Jordan serves us, we see that as comparative education entered the academy, it had already been identified with being a science. We must consider methods, methodology, and epistemology related to comparative education in the context of the broad landscape of higher education and mainly in the context of science. The *Encyclopedia of Philosophy*, for example, deals with the meaning of the terms method and methodology under the heading *scientific method* (Edwards, 1967).

The terms are inextricably associated with intentions of academic fields to be scientific. Bernard S. Phillips echoes most texts dealing with social science research as he defines the scientific method as “(1) defining problems so as to build on available knowledge, (2) obtaining information essential for dealing with these problems, (3) analyzing and interpreting these data in accordance with clearly defined rules, (4) communicating the results of these efforts to others” (Phillips, 1976). Robson also claims research strategies usually involve four levels: (1) research design, (2) methods of data collection, (3) analysis of the data, (4) and interpretation and implications of the analysis (Robson, 1993). There is a crucial difference between the terms methodology and methods in our research. The first and last of the strategies noted by Phillips and Robson rely so heavily on conceptual issues that they are mainly methodological in nature while only the second and third levels deal explicitly with methods.

When we refer to research methodologies, we refer to the larger context for methods being applied. In addition, methodologies usually have theoretical implications in that they provide theories of how research does or should proceed. There is a long methodological tradition in comparative education. The first academic comparative education scholars, such as Isaac Kandel, Nicholas Hans, and Friedrich Schneider, argued that education can only be understood within the context of broad economic, political, cultural, and social forces of a country. And their methodology demanded that educational systems not only be described in detail, but that the meaning of educational

phenomena be derived by interpreting the economic, political, cultural, and social conditions that defined the educational systems (Hans, 1955; Kandel, 1933; Schneider, 1961). This deems that education is not a separate or isolated aspect of society – rather it is deeply rooted within a society's political, cultural, and economic conditions.

As education came to be caught up in the drive to be more *scientific*, the methodological debates shifted to issues of the social sciences. One of the main issues comparative education scholars such as Brian Holmes and George Bereday argued over was whether research should proceed inductively or deductively (Bereday, 1960; Dewey, 1910; Holmes, 1965; Popper, 1963). The early scholars noted in the preceding paragraph took for granted that the process was inductive. Educational systems were described and then interpreted from the broader economic, political, cultural, and social context. Bereday's *comparative methodology* was also inductive in that it began with descriptions of two or more countries; then these systems were interpreted from the broader context. The next phase was to juxtapose the data for the countries. Finally, this data was compared. Clearly, their methodology was inductive in nature. Brian Holmes challenged this tradition by relying on people such as John Dewey and Karl Popper to expound on his so-called *hypothetico-deductive approach* to research and he criticized his colleagues for their tendency to begin the research process with descriptions of educational phenomena and only arrive at theory at a later stage in the process. This discussion is not dead and continues as a methodological issue in the debate over so-called *grounded theory* (Strauss & Glaser, 1967).

Methodologies are also related to the selection of research methods. The choice of data collection ought to be made on theoretical grounds and what data sources provide the most compelling evidence. This is particularly the case with regard to when and to what degree research ought to be qualitative or quantitative in nature (Crossley & Vulliamy, 1984; Heyman, 1979; Masemann, 1976). This issue focuses on the uses put to research. Robert Stake explains the different orientations of those doing qualitative research as opposed to those doing quantitative research: "Quantitative researchers have pressed for explanation and control; qualitative researchers have pressed for understanding the complex interrelationships among all that exists" (Stake, 1995).

Comparative education methodological issues also deal with the degree to which studies ought to be descriptive, interpretive, or prescriptive, or whether it ought to be melioristic, ideological, or strictly neutral (Kazamias, 1961), or the degree to which studies ought to be *problem based* (Holmes, 1965). Other methodological concerns involve the relationship between action and research, the relationship between the researcher and the object of research,⁴ or whether a single perspective or multiple perspectives are more appropriate (Kellner, 1988).

Methods have to do with how we collect and analyze data. When one decides on the methods of data collection, one is asking the following questions: what kind of information is being sought, from what sources, and under what circumstances? When one decides on how to analyze the data, one is deciding how to make sense out of the data that has been collected.

Science was particularly important in the development of comparative studies, and early comparative scholars uniformly identified their field as one which relied on the use of the *scientific method*. In the more general scientific sense, comparative scholars tested hypotheses about causal relations between phenomena. However, from the

beginning comparative scholars also restricted their scientific research in two ways. First, they examined similarities and differences between phenomena or classes of phenomena. Second, whereas science was generally committed to experimentation as a way of making classifications and testing theory, the comparative scholar relied almost entirely on studying variations in the natural setting.

We make no claim that comparative education studies are fundamentally different from social sciences in general. In fact, all social sciences are comparative in nature, at least insofar as all thought, especially considering that scientific thought is comparative in nature. The major complication of comparative studies is that it involves the analysis of “dissimilar units” (different societies and cultures) (Smelser, 1976). In comparative education the unit of analysis is usually the educational system or a subset of that system in two or more nation-states (Thomas, 1998). We recognize that no single research method or methodology has ever characterized the field of comparative education. Isaac Kandell, in his classic work, *Comparative Education*, explained that “the methodology of comparative education is determined by the purpose that the study is to fulfill.” In other words, Kandell assumed that different questions require somewhat different ways of answering them. However, our research projects at UCLA have confirmed that the types of research strategies available to people such as Kandell were rather limited, in that they focused mainly on historical and humanistic strategies.

Comparative Education Matures

Since comparative education entered the academy, it has undergone great change. In general, this change represents increasing complexity and diversity in the field. Such change represents both advantages and disadvantages, which we intend to discuss and interpret.

Internationalization of Comparative Education

Comparative education began as an academic field in the United States, but quickly developed a presence in Canada, Great Britain, Germany, and other European countries. This Eurocentric situation remained the major base of the field until the last quarter of the twentieth century, when programs and professorships rapidly began to expand to other parts of the world.

Erwin Epstein refers to this process as the internationalization of comparative education (Epstein, 1981). The expansion of the field is best illustrated by the growth of the World Council of Comparative Education Societies (WCCES) that was organized in 1970 to advance the field globally. WCCES has held 12 world congresses, the last being held in Havana, Cuba in 2004. At the time this essay was written in 2007, 33 different comparative education societies are listed as members of the World Council.⁵ In the literature, a number of accounts are found of comparative education in specific areas of the world. The United States claims the earliest account of its association origins (Templeton, 1954), but there are also historical accounts of comparative education in Japan, of Mainland China, of India, of Germany (Rust, 1967), of the former Soviet Union, of Europe in general (Cowen, 1980), and other geographic units. Gary Tsuchimochi claims comparative education in Japan was a direct outgrowth of World

War II, when the Japanese wished to gain access to the educational advantages the West presented to them (Tsuchimochi, 1982). Sureshchandra Shukla also feels India's interest in comparative education sprang from its colonial past, but also from an interest in understanding the educational conditions of its neighbors in China, Indonesia, and elsewhere (Shukla, 1983). The Chinese Comparative Education Society was established in 1979 with the intention that the Chinese educational community break away from its isolation with the rest of the world, so that it would learn from developments elsewhere, but also to disseminate research findings about educational developments in China (Chen, 1994). The former Soviet Union encouraged the development of comparative education within its sphere of influence, but its intentions were unique among comparative educators. It used education as a tool of propaganda in that the West was willing to publish articles written by Soviets, even though these articles glorified developments in the Soviet Union and castigated the West for its decadent, capitalistic educational policies and programs (Hans, 1964).

Expanding Scope of Research Options

The methodologies of early pioneers of the field were remarkably similar, in that no single method has ever characterized the field of comparative education. Although data collection research strategies several decades ago were limited to literature reviews and historical data, they increased dramatically over time. By literature reviews, we mean studies that are argued on the basis of secondary literature and could therefore be seen as interpretive essays. The more conventional social science approaches, such as interviews, ethnographies, participation/observation, questionnaires, and other types of field research has increased dramatically. In addition, one finds in comparative education journals additional strategies such as project reviews, content analysis of texts, analysis of census data, and other large survey databases.⁶

Expanding Scope of Data Analysis Options

Data Analysis in comparative education began almost exclusively as qualitative in nature. That is, the tradition was constructivist, interpretive, and naturalistic in that it was based on a paradigm that the researcher was continually interacting with the subject matter being researched and that the researcher was a part of the evaluation process. That process remains in reduced form even today, although a more positivistic, objective social science orientation has become a mainstay of the field. In fact, our work at UCLA indicates that the primary fields with which comparative educators today identify with are sociology, political science, and economics (Henrickson *et al.*, 2003). There remains a pervasive tendency to rely on qualitative data, but there has been a significant increase in quantitative studies since the mid-1960s. These quantitative studies are largely related with surveys and questionnaires.

Expanding Geographic Orientation of Research

The first major observation is that the geographic focus of comparative research has shifted dramatically from the 1960s until the present. In the 1960s comparative

education studies were largely focused on the developed world. In fact, in some areas of the world, comparative education was seen as something quite theoretical and separated from the developing world. At the University of London, for example, there was a clear separation between the comparative education program and the old Department of Education in Developing Countries, which was initially focused on colonial issues, then became generally concerned with “British foreign assistance projects and with training administrators and practitioners in the Third World...” (Altbach, 1991). This has changed, and even at the University of London, the two departments merged for a while as the Department of International and Comparative Education.

The geographic origins of scholars have also shifted. Early centers for the study of comparative education were staffed by specialists almost exclusively from the developed world. Thus, Brickman, Eggertsen, and Anderson were American; Hans was from Russia and of German descent; Kandel was Romanian and lived and taught in England and then the States; Bereday were Polish; Rosello was Swiss; Schneider and Hilker were German; Foster, Noah, Eckstein, Lauwerys (by birth, a Belgian), King and Holmes were English. Kazamias was Greek who was educated in England who later taught in the United States. Today, scholars increasingly originate from various parts of the world. They tend to come from countries falling in all spheres of human development, though because of the political economy of countries reflecting low human development, scholars from these countries are not as visible as scholars from other parts of the world, mainly because they do not have the resources necessary to engage in international research projects. Some remarkable developments can be observed. For example, in the 1990s China had no less than seven journals devoted exclusively to comparative education (Chen, 1994). According to a recent Nan Tou University bulletin in Taiwan, the university maintains six comparative education faculty positions, more than found at any American comparative education university center.

Theory in Comparative Education

Nowhere is greater change seen in recent decades than in theory. We have already noted that a liberal, humanistic tradition exemplified the early years of comparative education at universities, but this quickly gave way to endeavors to make comparative education a scientific enterprise. The theoretical foundations for comparative education shifted toward the social sciences, and the field was identified with two closely allied theoretical orientations: structural functionalism and modernization. Kazamias and Schwartz note that structural functionalism emphasized “social functions, societal interdependence, social order or consensus, and value free science” (Kazamias & Schwartz, 1977). In the comparative education context they feel it seeks to describe the interrelations between the educational system and other social institutions. Without question, structural functionalism stood alone as the pervasive sociological theory orientation of the period. It so dominated the landscape that it was simply taken for granted that any legitimate study of social forces and factors would be based on that orientation.

At the same time, comparative education was coming to devote itself to modernization, or the change process by which traditional societies would become modern. The mechanism by which this process would occur was seen to be schooling and education, and so comparative education became a central element in any modernization scheme (Altbach, 1991). A number of specific theoretical orientations came into play in modernization, including human capital theory, structural functionalism, and systems theory. Comparative education specialists were comfortable with their role in the modernization process, because the field had always had a reformist bent, a practical role in transforming not only education in any society but using education to transform society itself (Kazamias & Schwartz, 1977). This ambition had been central to many of the activities of those early reformists, who were anxious to influence others across cultures through educational reform.

By the 1970s, the domination of structural functionalism and modernization precipitously declined, as the hegemonic domination of earlier theoretical orientations was successfully challenged. The major challenges came from a wide array of “emergent critical and interpretive knowledge communities” (Paulston, 1993), which were attempting to change America into a more open, pluralistic society. If they were not successful in transforming society, they were certainly successful in changing academic environments, including comparative education.

With the decline of the hegemonic impulses of the 1950s and 1960s, comparative educationists became increasingly theory oriented, in large part because the journals publishing comparative education works reflected an increasing number of theories. In addition, our work at UCLA confirmed that authors included multiple perspectives in their work. In our inquiries of authors of comparative studies, we compiled a list of at least 26 different theoretical orientations authors publishing in major comparative education journals were relying on.⁷

We must emphasize that scholars who rely on and develop theory are generally committed to science. We have found that almost all of the people contributing to comparative education journals are committed to theory, and those few scholars who deny their work is theory-driven see their work as descriptive and practice-oriented. They are “profession-” more than “academics”-driven.

One of the major concerns that have been raised over the years is the lack of unity in comparative education. Surely, at the time the field entered the academy, there was a sense of unity with regard to the disciplines in the field, the geographic focus, the origins of the early comparative education scholars, the methodology, and the theoretical orientation. Over time, this unity has been lost, and there has been some concern that the field has begun to spin out of control and fragment itself in all of the above respects to the point that it may have little coherent identity.

From our vantage point we see the field becoming pluralistic rather than fragmented, and that pluralism can be seen as a strength in that it indicates a break from the stifling orthodoxy, that characterized the field in the 1950s and early 1960s, both theoretically and methodologically. However, any phenomenon that gyrates has the potential of spinning out of control, losing any sense of the identity and cohesiveness necessary for a field to grow and thrive. This is certainly not yet the case; we see comparative education as a healthy, defined field of endeavor.

Where Is Comparative Education Headed?

It is our general perspective that comparative education is in a state of good health; it is now opting for directions that introduce a fresh perspective for those who have been in the field for several decades. This is being highlighted by comparative education students just entering the field. The field reached a decisive and optimistic point in the late 1960s, with the publication of *Toward a Science of Comparative Education* by Harold Noah and Max Eckstein. The general tone of the book was that the field was finally establishing itself as a legitimate science. The authors catalogue various phases of the field, including travellers' tales, educational borrowing, international educational cooperation, forces and factors shaping education. All of these were "predecessors of modern comparative education" (Noah & Eckstein, 1969).

Discourse about modern comparative education inherently encompasses the notion of globalization. Val Rust addressed the intersection of education and globalization in his publication *Foreign Influences in Educational Reform*, which raises the question as to whether or not research in the field of comparative education has been able to keep up with the rapid progression of globalization. Rust cites three categories of educational response to globalization – receptivity, resistance, and restoration (Rust, 2004).

Receptivity, also referred to as "cross-national attraction and borrowing," is the process through which education communities respond positively to external influences by adopting aspects of other educational systems with the desired objective of improving their own. This has been the main concentration of the field since its origin. The second response by education communities is resistance. Advocated by radical theorists, resistance attempts to counter the oppressive, capitalist forces of neo-liberal globalization through concerted efforts to maintain and celebrate differences in cultures, languages, and political ideologies. Throughout the world, cultural imperialism, a consequence of colonialism and now globalization, has been responsible for the decline and decimation of countless indigenous languages and cultures. Restoration, the third identified response, is initiated to ensure the preservation and promotion of such indigenous knowledge.

Receptivity, resistance, and restoration adequately portray a historical focus of comparative education. However, as up and coming professionals in this field, the junior authors of this essay feel there has been a lack of focus on the oppressive nature of the forced imposition of educational programs or requirements from dominant to dominated countries in non-symbiotic relationships, which has been the trigger for educational resistance and restoration. This relationship between dominant and dominated countries is substantially different from Rust's description of "reception theory," and we feel that another category should be considered within the field of comparative education. Such a category is comparable to the theory of reproduction, in which "schools function in the interest of the dominant society" (Giroux, 1983). Whereas receptivity reflects the internal efforts to improve an educational system by incorporating selective aspects of external systems, reproduction is the forced implementation of educational systems by an external, dominant society. In this case, the "dominant society" refers to the developed or core countries, with a "hidden curriculum" of promoting the dominant, core culture and maintaining a relationship of inequality and

dependency. This is a significant consequence of globalization that needs the full attention of future comparative education researchers.

Mainstream comparative education has conscripted the advancement of modernity as the underlying definition of education. As new professionals in the field, we challenge this notion and urge progressive comparative educators to cooperatively consider a meaning of education that advances humanity instead of modernity. As part of this consideration it is necessary to pose the question, has mainstream comparative education promoted a liberating “education” or rather a hegemonic neo-liberal political ideology? Paulo Freire states unambiguously that education is politics (Shor & Freire, 1987). By promoting modernity, comparative education has sided with the capitalist economic model, which Freire describes as having “absolute insensitivity to the ethical dimension of existence” (Freire, 1998). What comparative education requires is a shared discourse about the political forces that have infused modernity into the definition of education. A brief consideration of UNESCO’s Education for All (EFA) initiative provides the impetus for this discourse.

The EFA goals, as accepted almost universally, represent a meaningful and comprehensive humanist-based definition of education, which emphasizes educational equity, access, and literacy. Based on the latest quantitative evaluation of EFA by UNESCO, almost none of the African, Middle Eastern (with the exception of Israel), non-English speaking Caribbean, or Latin American countries, many of which had been coerced into adopting capitalist-based educational systems, have yet met their EFA goals (UNESCO, 2006). The notable exception is Cuba, which has succeeded by working outside of the dominant global capitalistic structure. Disappointingly, Cuba has not received any distinction for achieving the EFA goals due inevitably to its marginalized status for not supporting the dominant capitalist ideology. Considering that EFA promotes a humanistic educational outlook, Cuba should be applauded for its achievement in realizing the EFA goals and be considered as a model for other countries.

Comparative education, in a historical context, has provided a strong foundation for international cooperation for the advancement of receptive education. However, neglecting the reproductive aspect of mainstream comparative education has led to the necessity of resistance and restoration. The recognition of the latter two should have been a warning sign that the focus and interventionist approach of the field has resulted in non-symbiotic international relationships and an increasingly dependent and exploitative global community. As up and coming comparative educators, we concur with Arnove’s statement, “We believe that comparative education can – and *should* – play a significant role in contributing to the possibility that coming generations will use their talents on behalf of international peace and social justice in an increasingly interconnected world” (Arnove, 1999). In order to play this role, comparative education would do well to return to its roots. Isaac Kandel, the previously mentioned pioneer in the field, wrote in 1955, “Because a nation seeks through education to mould the character of its citizens and so reflects its aims – political, social, economic, and cultural – a study of its educational system, as here defined, can contribute as richly to an understanding of its aims in general as a direct study of its political policies” (Kandel, 1955). With this understanding of comparative education as a field dedicated to research and receptivity, not interventionism and reproduction; with the acceptance

that education be defined in terms of humanism, not capitalism; and with a praxis of liberation, not domination, individual countries and societies can take ownership for defining their own educational systems for the benefit of their people, culture, economics, and politics.

Notes

1. The first professors of education were appointed in Scotland in 1876. Simon Somerville Laurie received the appointment at Edinburgh and John Miller Dow Meiklejohn at St. Andrews. William H. Payne was the first in the United States in 1879 at the University of Michigan. At the time of his appointment, William H. Payne had been serving as the superintendent of Adrian School District in Michigan, and it is significant that the very first lectures he gave at the University of Michigan were on the schools and the educational systems of Europe. Of course, the term comparative education was not in use at the time (see Payne, 1887).
2. Auguste Comte, father of sociology, initially named the field “comparative sociology” (see Comte, 1988).
3. (Jordan, 1905: 35). The fields Jordan discussed were Comparative Anatomy, Comparative Philology, Comparative Grammar, Comparative Education, Comparative Philosophy, Comparative Psychology, Comparative History, Comparative Geography, Comparative Antiquities, Comparative Art, Comparative Architecture, Comparative Agriculture, Comparative Forestry, Comparative Statistics, Comparative Ethnology, Comparative Mythology, Comparative Sociology, Comparative Hygiene, Comparative Hygiene, Comparative Physiology, Comparative Zoology, Comparative Jurisprudence, Comparative Economics, Comparative Colonization, Comparative Civics, and Comparative Politics.
4. There are some wonderful essays from feminists about the dilemmas they face in international work (see, for example, Cook & Fonow, 1991; Wolf, 1996).
5. See <http://www.hku.hk/cerc/wcces.html>
6. For specific information concerning these strategies, see (Rust *et al.*, 1999)
7. These included human capital, modernization, structural functionalism, systems theory rational choice, political pluralism, organizational/institutional theory, dependency, Marxian/neo-Marxian, World systems, ethnography, phenomenology, constructivism, symbolic interactionism, critical theory, cultural revitalization, feminism, post-structuralism, post-modernism, pragmatic interactionism, and neo-colonialism (see Henrickson *et al.*, 2003).

COMPARATIVE EDUCATION: HISTORICAL REFLECTIONS

Andreas M. Kazamias

Time present and time past are both perhaps present in time future. And time future contained in time past (T.S. Eliot).

Prologue

The term comparative education (CE) is not a mono-faceted or monophonic concept/intellectual system. It is an inter- and multidisciplinary ‘human science’, an *episteme* in Nicholas Hans’ sense of *Vergleichende Erziehungswissenschaft* (Hans, 1959: 299). Historically, the genealogical roots of CE have been traced to the ‘modernist’ epoch of the European Enlightenment of the late eighteenth and early nineteenth centuries. Since that time, comparative studies of educational systems, problems, phenomena or processes have been conceptualised, approached and constructed from a variety of perspectives, through a variety of methodological prisms/lenses, and using a variety of research methods and techniques. Like the Greek mythical demigod Proteus, CE at different historical periods has donned different attire, woven by differently coloured epistemological, methodological and ideological threads. Consequently, it has appeared in a variety of guises reflecting to a large degree, the intellectual, methodological and cultural strands and fads of the times. Hence, the appellation of CE as a *protean episteme* (Kazamias, 2001). To put it differently, in reflecting historically on CE as a ‘human science’, as this chapter purports to do, I shall ‘theorise’ about ‘generations’ and ‘types’ of comparative education discourse.

The ‘Proto-Scientific’ and the Administrative ‘Meliorist’ Generation of Comparative Education Discourse

Conceptualised as a ‘modernist’ episteme, the beginnings of CE have been traced to the intellectual and cultural terrain of the European Enlightenment of the late eighteenth and the early nineteenth centuries. Among the cluster of ideas assumptions and expectations, that have gone into the construction of the Enlightenment ‘paradigm’, or what has otherwise been referred to as the ‘project of modernity’ are taken to include reason, empiricism, science (including social science), universalism, progress, and the

nation state. It is in the intellectual and institutional matrix of the Enlightenment era that modernist *epistemic* elements of CE may be historically traced. This is manifest, for example, in the pioneer efforts of Marc-Antoine Jullien de Paris (1775–1848) who sought to construct an empirically based ‘nearly positive science’ of CE, one that would provide ‘non-arbitrary’ and ‘non-capricious’ knowledge for ‘the reform and improvement of education’. In his *Esquisse et vues preliminaires d’un ouvrage sur l’éducation comparée (Plan and preliminary views for a work on comparative education)*, published in Paris in 1817 and unearthed in the 1940s, Jullien laid out what may be called a ‘proto-scientific’ paradigm of comparative education:

Education, as all other sciences and all the arts, is composed of facts and observations. It, therefore, seems necessary to form, for this science as one has done for the other branches of knowledge, collections of facts and observations, arranged in analytical charts, which permit them to be related and compared, to deduct from them certain principles, determined rules, so that education might become almost nearly a positive science. Researches on *comparative anatomy* have advanced the science of anatomy. In the same way the researches on *comparative education* must furnish new means of perfecting the science of education (Fraser, 1964: 40–41).

The scientific template and culture of the Enlightenment, which must have informed Jullien’s ‘preliminary views’ towards the construction of his Plan for what may be called the prototypical social science of CE, were not restrictive in their scope and signification, namely, the production of ‘reasoned and empirically based knowledge’. Social science, according to the intellectuals of the Enlightenment, was bound up with the concept of progress. These reformist significations, social ideas and values (i.e. social and moral meliorism, liberalism and humanitarianism) were integral constituent parts of what may be called the ‘proto-modernist comparative canon, which is more fully discussed in another chapter of this Handbook by Pella Kaloyiannaki and Andreas M. Kazamias.

The Nineteenth-Century Administrative Melioristic/Reformative Motif, European-French and American

As noted in other historical accounts of comparative education, the ‘scientific’ and universalistic elements of this proto-modernist/‘proto-scientific’ generation of comparative discourse were not fully inscribed onto the *epistemic* template of CE in the nineteenth century (Kazamias & Massialas, 1965; Fraser, 1964; Noah & Eckstein, 1969; Jones, 1971; Tretheway, 1976). For the most part, what one observes in the nineteenth century was another generation of comparative discourse, which was more ‘international’ than ‘comparative’ in that it dealt with ‘foreign education’ or education in other countries, with only incidental, if at all, comparative references. Some of the notable representatives of this discourse were Victor Cousin in France and Horace Mann, John Griscom, Calvin Stowe, Henry Barnard and W.T. Harris in the United

States. These ‘international’ educationists sought to gather information and data on aspects and problems of foreign education that were of immediate concern to them in their roles as policy-makers and administrators in their respective countries or ‘states’. Their overriding consideration was to see what useful ideas and practices they could ‘borrow’ for the reform of their own system. In the case of most Americans, such ‘borrowed’ ideas and information were used as legitimising rationales for mainly politico-ideological, melioristic and reformative purposes. As we have written elsewhere (Kazamias & Massialas, 1965), some of these characteristics (e.g. meliorism, reformism and, we may add, nation-state formation) were present in the previous generation. Indeed, they were germane to the spirit and culture of the Enlightenment, and *pari passu*, to the ‘modernity project’. Such elements went into the making of the ‘quasi-ethnographic’, ‘quasi-historical’ and descriptive national reports by mainly practically minded school administrators, policy-makers and policy-advisers such as Horace Mann, Henry Barnard, Calvin Stowe and William T. Harris of the United States, Victor Cousin of France, and Mathew Arnold of England, to name but a few of the better-known ones (Holmes, 1965; Kazamias & Massialas, 1965; Noah & Eckstein, 1969). Of these comparativists, however, the views of Sadler and to a degree those of Harris are especially illustrative of this transitional generation of discourse. For, although their studies/reports on foreign systems of education were for the most part descriptive, ‘scholiocentric’ (i.e. centred in aspects of the school system, of schooling and of pedagogy as isolated institutional and socio-cultural phenomena) and hortatory, these writers can also be credited with adumbrating a new comparative *epistemic* discourse.

In his much-quoted Oxford address of October 20, 1900, entitled ‘How Far Can We Learn Anything of Practical Value from the Study of Foreign Systems of Education?’, Michael Sadler framed the conceptual template of the emerging historical-meliorist and cultural canon in these words:

Therefore, if we propose to study foreign systems of education, we must not keep our eyes on the brick and mortar institutions, nor on the teachers and pupils only, but we must also go outside into the streets and into the homes of the people, and try to find out what is *the intangible, impalpable, spiritual force* which, in the case of any successful system of Education, is in reality upholding the school system and accounting for its practical efficiency...; In studying foreign systems of Education we should not forget that *the things outside the schools matter even more than the things inside the schools, and govern and interpret the things inside. A national system of Education is a living thing...* *The practical value of studying, in a right spirit and with scholarly accuracy, the working of foreign systems of education is that it will result in our being better fitted to study and to understand our own* (Sadler, 1900, reprinted in Bereday, 1964: 309–10, italics mine).

And in another context, Sadler wrote: ‘The educational question is not a question by itself. It is part of the social question. And the social question is at bottom largely an ethical question’ (quoted in Noah & Eckstein, 1969: 47).

In these discursive statements, Sadler brings together most of the epistemological and methodological strands that went into the making of the ‘historical-meliorist’ form of comparative education that emerged from the social, cultural and intellectual context of the late Victorian period which also marked the waning of an era – a *fin de siècle* – and the dawn of another. These strands can be summarised as follows:

- (a) Educational questions are not ‘scholiocentric’; hence, schools and schooling must be studied in the context of the societies in which they function.
- (b) The primary aim of comparative study is, ‘in a sympathetic spirit, to understand the real working of a foreign system of education’, not to judge it.
- (c) In order to understand the workings of an educational system, however, one must try and find out the historical, non-school ‘intangible, impalpable spiritual force’ that moves it and gives it its national character and identity; one must probe into ‘the secret workings of national life’.
- (d) In comparative education one studies foreign systems of education, and the focus is on national systems and on national education.
- (e) The ‘practical value’ of a scholarly study of other national systems of education is that it will help us ‘to study and to understand our own’.
- (f) Lastly, it could also be said that by making us better fitted to understand our own system of education, the study of foreign education would have the added value of helping us to improve it.

Some of these strands are to be found in the reports of continental European education by Mathew Arnold, the Victorian poet, essayist, literary, social and cultural critic, apostle of Eurocentric ‘high culture’, and Her Majesty’s Inspector of Schools. However, as an inquiring reporter on European education and culture, Arnold, the ‘comparative educator’, emphasised types of discourse that were either excluded or lay hidden in the writings of his predecessors and his contemporaries. For example, he used the experience of other European nations, e.g. France, as an exemplar of what might be done in his own nation, i.e. in England, and comparison as an aid to criticism of the English polity, society, culture and education. In this connection, it is significant and, considering Arnold, the Victorian liberal intellectual, rather ironic to note that he condemned the then dominant ideology of *laissez-faire liberalism* and its political doctrine of a ‘minimal state’. Referring to the French polity and culture, which he had found more democratic than the English, he argued for greater state interference at home. Arnold, in other words, grappled with ‘state-steering in education’ and, more broadly, in *culture*.

This new generation of comparative discourse, what we have called the ‘historical-meliorist’ and ‘liberal humanistic’ canon, emerged in and formed part of a world, a *cosmos* that in many respects was different from the world of the Enlightenment. It was a polymorphous, tension-ridden and uncertain socio-political, economic, intellectual and cultural *cosmos* made up of a motley of human actors: ‘laissez-faire liberals’, ‘liberal democrats’, ‘radicals’, ‘conservatives’, ‘welfare statist’, and even ‘collectivists’, elitists and egalitarians, ‘barbarians’, ‘philistines’ and the ‘populace’ (to use Matthew Arnold’s classic sociological-anthropological description of the English industrial bourgeois society and culture); romantics, humanists and rationalists; macro-historical

functional and conflict social scientists; optimists and nihilists; Christians, moralists and sceptics; nationalists and imperialists.

The Historical-Philosophical *cum* Liberal-Humanist Generation of Comparative Discourse

It is in this new and variegated multicultural *mosaic* of the ‘modernity project’ that the revised ‘paradigm’ of comparative education, represented by Michael Sadler, was generated and took the modernist form that it did, what could be described as the ‘historical-philosophical’ cum ‘liberal-humanist’ form. However, it was left to a succeeding generation of comparative educators, foremost among whom were historian-philosophers and liberal humanists like Isaac Kandel and Robert Ulich in the United States, Nicholas Hans in Great Britain, and Friedrich Schneider in Germany, to construct and help institutionalise CE as a ‘historical-philosophical’ and ‘liberal-humanist’ explanatory/interpretive *episteme*. Here we shall sketch the distinctive intellectual/epistemological and methodological contours of this generation of comparative discourse drawn from the works of Kandel, Hans and Ulich.

- (a) Comparative education, according to Hans, entails the identification of the ‘factors’ – social, political, economic, cultural – which have gone into ‘the creation of different nations’ and different ‘national systems of education’. Such factors have included: natural factors (race, language, environment – mainly geographic and economic), religious factors (catholicism, anglicanism and puritanism), and secular factors (humanism, socialism and nationalism). Hans adds: ‘The analytical study of these factors from a historical perspective and the comparison of attempted solution(s) of resultant problems are the main purpose of comparative education’ (Hans, 1949: 9–11). Kandel injected an ‘idealist’ philosophical element in this historical approach by conceiving CE to be an inquiry into the history of ‘ideas, ideals and forms’. He wrote:

The chief contribution then, of the study of comparative education is that, if properly approached, it deals ‘with fundamental principles’ and fosters ‘the acquisition of a philosophic attitude’ in analyzing and therefore stimulating a clearer understanding of the problems of education. The study makes the educator better able to enter into the spirit and tradition of the educational system of his own nation (Kandel, 1955: 12; Kandel, 1933: xx).

And in language that echoed Michael Sadler, as well as contemporary philosophical humanists, he searched for ‘the hidden meaning of things found in the schools’, and he called for ‘an appreciation of the intangible, impalpable, spiritual and cultural forces which underlie an educational system’ (Kandel, 1933: xx–xv, 1955: 8–12).

- (b) Comparative education is not an ‘empirical social science’. It is an interpretive/explanatory and a ‘melioristic’ *episteme*. It is neither a predictive nor a policy-oriented social science. In the tradition of the earlier generation of discourse,

especially in the work of Kandel, it is ‘melioristic’ in the sense that the knowledge, insights and understandings acquired through the historical-philosophical-humanistic comparative approach would help develop a ‘a broad philosophical attitude’ that would help in the improvement of education at home and abroad, and, ultimately, it would foster the spirit of internationalism (Kandel, 1955: 12, 1933: xx). As we have written elsewhere, being an idealist, Kandel was more concerned with ‘form’ than with the details that make up a national system of education. Such ‘form’ could be grasped through study of the ‘history and traditions ... the forces and attitudes ... the political and economic conditions that govern the social organization and determine the development of an educational system’ (Kazamias & Schwartz, 1977: 156; Kazamias & Massialas, 1965: 3).

- (c) An essential aspect of Kandel’s notion of understanding, as indeed of Hans’ and Ulich’s, was the ‘national’ or national-state context of human and educational activity. His, as well as their units of analysis were national systems of education: English, German, French, Russian, American (USA). All of them were explicit in their accounts that schools and educational practices were influenced by national traditions, national political ideologies, and the ubiquitous, at the time, ‘national character’ (Kandel, 1933: xxiv).
- (d) Not only could CE be a positive force for the improvement of education and the fostering of ‘internationalism’; it could also be a positive force for the development of ‘liberal democracy’ and ‘democratic citizenship’. The comparative work of Kandel, Ulich and Hans was infused with ‘Eurocentric’ and Western liberal democratic ideas and principles about the polity and the economic system, about the nation state and civil society, about the role of the individual and the state and about ‘liberty, equality and fraternity’. And in the spirit of the ‘Enlightenment modernity project’, all three had an abiding faith in the idea of progress, and progress through enlightenment and education. In this connection, it would not be inappropriate to note that Kandel was born a Rumanian Jew, who abhorred Nazism and considered all forms of authoritarianism and totalitarianism, especially the Soviet type, as ‘blasphemous anathema’; Ulich was a German émigré to the United States, who had escaped from Nazi Germany in the 1930s; and Hans was also an émigré from Eastern Europe.
- (e) Lastly, the conceptual tapestry of this generation of comparative discourse was marked by the prominence given to the political element – the political relations of schooling – and specifically in the work of Kandel, to the concept of the ‘state’. In the Kandelian *episteme* of comparative education, the state, by which he meant the ‘nation state’, was a determining factor in categorising, understanding and evaluating national systems of education. ‘As is the state, so is the school’, and conversely, ‘As is the school, so is the state’, or, stated otherwise, ‘Every state has the type of education that it wills’ (Kandel, 1933: 82, 1955: 21).

Re-Inventing the Social Scientific Canon

In the late 1950s and early 1960s, the nature, scope, methodology and value of CE as the modernist *episteme* presented above, came under intense scrutiny and reassessment.

A group of young scholars, some of the more prominent of whom were nurtured in the Euro-American Eurocentric intellectual tradition, questioned the then dominant historical approaches and other 'international' activities that went by the name of CE, namely, descriptive and/or impressionistic accounts of foreign systems of education. Calls were made for approaches that would be more systematic than impressionistic, more empirical and analytical than purely speculative and descriptive more 'microcosmic' than 'macrocosmic' and Olympian, and more 'scientific' than 'historical' or 'philosophical'. An unprecedented output of articles on the theory and method of CE appeared, no less than 25 in the newly established *Comparative Education Review* alone during the period 1957–1965. In addition to the *Comparative Education Review*, an American-based Comparative Education Society was established, and all major universities in England and the United States set up comparative education departments or units, all of which sought to promote the study of CE and elevate its status as a respected academic discipline.

In the ensuing years, the ferment of controversy over the epistemological and methodological contours of the field continued unabated: whether CE was an art, a science or a combination of both; whether it was a discipline in its own right or an area of study on which several disciplines were brought to bear; whether it was a theoretical or an applied activity/*episteme*; or whether its techniques of analysis should be empirico-statistical, historical or philosophical. Concurrently, the controversy revolved around the appropriate subject-matter of CE – whether, for example the emphasis should be on school-centred problems or on school–society relationships.

In the mid-1950s, it was possible to identify individuals who were recognised as authoritative spokespersons for CE, and texts which defined its parameters and codified its subject matter. Such was the case, for example, with Kandel and his books *Comparative Education* (1933) and *The New Era of Education* (1955) and N. Hans with his *Comparative Education: A Study of Educational Factors and Traditions* (1949). Twenty years later, in the mid-1970s, such identifications were no longer possible.

In 1977, the *Comparative Education Review* (of which the present writer was the editor), the official scholarly journal of the Comparative and International Education Society, put out a special issue on 'The State of the Art'. The cover of this edition was adorned by a cartoon showing a reflective Humpty Dumpty sitting, with his short legs hanging down, atop a sketchy map of the United States. With a pondering look on his disproportionately large face, Humpty Dumpty gazed at what was inscribed on the map: *structural-functionalism, cost-benefit, production, pedagogy, development, mankind*. This cartoon graphically symbolised some of the dominant themes that went into the making of the *episteme* of CE in America in the post-Kandelian, post-Hansian period of the 1950s and 1960s period, at least as this intellectual field was conceptualised and cultivated by some of the major contemporary writers. Such features reflected quite a different 'generation of comparative discourse' from the previous one depicted above. One may interpret this 'modernist' form of comparative discourse as a reinvention of the 'scientific' tradition inaugurated by Jullien during the period of Enlightenment. I shall refer to this generation as the era of 'scientism', an era characterised by a frenzy of activity to make CE a 'science', and a positive and predictive social science at that. The 'historical-philosophical-humanist' school, was, by and large, judged by prominent people in the field to be 'unscientific' and, therefore,

neither productive of objective and reliable knowledge, nor particularly helpful for purposes of theory-building, educational policy formation, development, modernisation and educational planning. Historical comparative education, as promulgated by Kandel, Hans and Ulich, for all meaningful purposes, was according to that new scientific school interred with their bones.

The reinvented and redefined scientific comparative ‘paradigm’ appeared in a variety of epistemological and methodological guises or forms, and it permeated both the theoretical and the practical comparative discourse in the immediate decades after the 1960s. To a large extent, what may be called the ‘neo-scientific’ comparative canon in its various forms continued to permeate much of the discourse in the 1980s and after.

Functionalism: The Functional-Sociological Chicago School

The most salient and pervasive form of the ‘neo-scientific’ generation of comparative discourse in the Anglo-Saxon world was the multifaceted paradigm of functionalism (Kazamias & Schwartz, 1977; Kazamias & Massialas, 1982). Originally associated with the eminent anthropologists Malinowski and Radcliffe-Brown, structural-functionalism was developed and applied to American sociology by its greatest representative Talcott Parsons. By the 1950s, according to Floud and Halsey, it became the prevailing orthodoxy in American sociology of education (Halsey *et al.*, 1961). C. Arnold Anderson, the founder of the University of Chicago structural-functional school of thought, was nurtured in the American structural-functional school of sociology, while Philip Foster, another member of the Chicago School, had studied economics, sociology and anthropology at the University of London (the academic habitat of Malinowski), and had completed his graduate education under Anderson at the University of Chicago.

At the risk of oversimplification, it may be said that functionalism in CE examines the social, political and economic functions or relations of schools and schooling. It emphasises societal functional interdependence (i.e. interrelations between the educational system and other societal sub-systems), and, the ‘equilibrium’ variant of it, social order or consensus and value-free ‘scientific’ enquiry.

Some general tenets of the functionalist framework – namely, that education does not function *sui generis*; it is interrelated with other social and political institutions, and it can best be understood if examined in its social context – have been espoused by most educational comparativists. Certainly such features can be found in many of the well-known works in the field, especially the classic historical studies of Kandel (1933, 1955) and Hans (1949).

In contrast, however, to the ‘historical functionalism’ of Kandel and Hans, CE in the 1960s and 1970s was characterised by the following traits: (1) efforts to ground the study of education in scientific, empirical, mostly quantitative methods and techniques; (2) a quest for ‘invariant’ and ‘timeless’ relationships and thus the assumption that it is possible to develop a theory of education; (3) a focus on the actual role of schooling in social, political and economic processes, as in socialisation (including political socialisation), social selection or social differentiation, recruitment of elites, social or national integration, human resource development, and the like; (4) a view of educational change as essentially ‘reformist’ or ‘adaptive’, that is, a process of adaptation

of educational structures and forms to changes in other sectors or subsystems of the social order; and (5) a vision of the modern society – ‘meritocratic’, ‘democratic’ and ‘expert’ – towards which socio-educational developments should strive (Hurn, 1978; Karabel & Halsey, 1977).

The rise of the functional paradigm in CE coincided with a variety of other intellectual currents: the prevalent school of American sociology (Parsons, Merton), British social anthropology (Malinowski, Radcliffe-Brown), human capital theory and its corollaries (Schultz, Harbison and Myers), theories of development and modernisation (Levy, Lerner, Rostow, McClelland and Black), and the political culture and system analysis schools of thought in political science (Coleman, 1965). At the same time, functionalism and social theories of educational change or modernisation, as well as policy recommendations based on functionalist analyses, were a response to the socio-economic and political conditions of the times and were reinforced by institutional and/or individual support from governments, foundations and international organisations for promotion of their own policy interests.

The functionalist paradigm in the emerging ‘neo-scientific’ CE of the 1960s was most apparent in productive research on the social, political and economic relations/functions of education. Themes investigated from the functionalist perspective included, inter alia: (a) the structure and context of educational opportunities and inequalities, (b) the mechanisms of educational recruitment, selection and discrimination, (c) the role of education in development and modernisation (social, political, economic), (d) education, political socialisation, political integration and nation-building, and (e) education and economic growth (Kazamias & Massialas, 1982).

Of these ‘problem areas’, that of ‘education-development-modernisation’ constituted a wide range of activities both inside and outside the halls of academia. One distinguishing feature of this perspective was the ‘instrumental-developmental’ conception of the role of education and its extension into the development of strategies (policies and plans) for change and reform. Scientific inquiry, according to this approach, could instruct us not only to understand the problematic of the education-development-modernisation nexus; it could also provide solutions or guidelines for change and improvement. Developmentalists held the view that education is a determining factor in improving the conditions of people. To quote a contemporary apophthegm: ‘Education is the key that unlocks the door to modernisation’. The functionalist paradigm, it should be re-emphasised, informed much of the literature – and there was a great deal of it – that approached education through the theoretical lenses of modernisation and development, as well as, it may be added, the literature that approached education from a systems-analytic perspective.

Methodological Empiricism, Methodologism, and Scientific ‘Modernism’

The other approach or ‘research strategy’ to ‘scientific’ CE was what we have elsewhere called ‘methodological empiricism’ (Kazamias & Schwartz, 1977: 173–175) and what B. Barber has called ‘methodologism’ (Barber, 1972). This intellectual perspective was elaborated in the writings of H. Noah and M. Eckstein, two influential comparativists during the period under consideration. In many respects, it also pervaded the work of

G. Psacharopoulos, an influential economist of education, who, studied at the University of Chicago and, subsequently, operated within the intellectual tradition associated with the Chicago school of ‘human capital theory’ (Psacharopoulos, 1987). Central to this ‘scientific’ approach was a ‘monistic’ view of science and the assumption, in the words of Stephen Toulmin, that there is ‘a single, all purpose “scientific method”’ (Toulmin, 1963: 15–17). Calling for the transformation of CE into a ‘pure social science’ akin to methodological developments in other contemporary social sciences, Noah and Eckstein advocated a comparative *episteme* that would conform to all the requirements of ‘scientific modernism’ or simply ‘scientism’, namely, hypothesis-formation and hypothesis-testing, verification, control, explanation, prediction, quantification, positivism and theory construction. In their influential *Toward a Science of Comparative Education*, published in 1969, Noah and Eckstein cite the work of the newly established Council for the International Evaluation of Educational Achievement, later called the International Association for the Evaluation of Educational Achievement (IEA), as an example of what they meant by ‘science of comparative education’. The epistemological and methodological perspective of the newly initiated IEA research project was described and exemplified in the much-publicised and acclaimed two-volume *International Study of Achievement in Mathematics*, edited by Torsten Husén and published in 1967. ‘In the IEA project’, Noah and Eckstein wrote in 1969, unlike previous ‘original efforts of social scientists making a contribution to the growth of comparative study in education, . . . the stimulus to cross-national research comes from educators and psychometricians who have enlisted the skills of empirically-oriented social scientists’. And, significantly for our purposes here, they elaborate on their brand of ‘scientific comparative education’:

As a result, preoccupation with scientific methodology emerges as an increasingly dominant theme in the latest stage of comparative research. There is a growing readiness and ability to employ the essential elements of scientific method. Heightened recognition is being given to the importance of hypothesis formulation and testing; the concept of controlled investigation through careful selection of cases is being developed; much attention is being paid to precise specification of variables and to qualification of the indicators by which they may be decided. Finally, researchers are becoming accustomed to seek quantitatively expressed explanations of the relationships between variables (Noah & Eckstein, 1969: 789).

Commenting on the IEA type of comparative research a few years later, Max Eckstein noted that ‘in many respects [the IEA effort] is a realization of Jullien’s outline of a century and a half ago of what comparative education might be’ (Eckstein, 1977: 350).

The social scientific paradigm of CE advocated by Noah and Eckstein contrasts sharply with the traditional historical paradigms which held sway until the mid-1950s. In some aspects it was also different from the functionalist social scientific approach, at least the brand of functionalism advocated by Philip Foster of the Chicago School. For one thing, the Noah and Eckstein brand of CE research was thoroughly ‘ahistorical’, which was not the case with the functionalist approach as exemplified by

Foster in his study *Education and Social Change In Ghana* (1965). More importantly, the challenge of the Noah and Eckstein style of social-scientific comparative study, as stressed by Noah in another statement in 1973, was ‘to move from the particular to the general, from identification-description-classification to hypothesis-testing, theory building and prediction’. In such an effort, an attempt is made to establish law-like, ‘cross-system statements’ or generalisations by replacing ‘names of systems’ or observable facts by ‘names of concepts (variables)’. Here are two examples that according to them exemplify the type of ‘law-like’ statement that social-scientific comparative research should seek to establish. One example refers to a cross-national investigation into ‘the relationship between the size of a family’s income and the probability of the children in the family enrolling in the full-time post-secondary education’:

In all countries, size of family income is positively associated with the probability of children in the family being enrolled in full-time post-secondary schooling, and differences in family income can explain at least one-half of within-country differences in the probability of enrollment. In all countries where income inequality and the proportion of costs defrayed from non-tuition sources are low, the explanatory power of differences in family income rises to at least three quarters. Consideration of the fraction of the age-group graduated from secondary education, and the recency of growth of the post-secondary system does not improve [the] explanation appreciably in any case except in the Soviet-type countries, where there factors do seem to be important (Noah cited in Marshall, 1973: 91–94).

Another important illustrative example of what Noah and Eckstein meant by comparative education as ‘pure science’ referred to the much researched question of educational reform and development. In such a case, according to them, the ‘pure scientific’ researcher, in contrast to the ‘applied researcher’ is less concerned with particular questions such as ‘Why did the plan for educational development fail in India?’ or ‘Why is there a shortage of teachers in Nigeria?’ and more with general questions such as ‘what are the conditions for the success of educational reforms?’ and ‘What are the factors which influence the supply and demand of teachers?’ (Noah & Eckstein, 1989: 104).

Such a ‘modernist’ view of science, according to Barber, assumes an objective, value-free form of inquiry; it presumes that ‘reliability, precision and certitude can be attained by the dutiful application of specific methods and techniques – irrespective of the nature of the subject under study’ (Barber, 1972: 425); and it ‘views science as axiomatic and mathematical and takes the realm of science to be separate from the realm of form, value, beauty, goodness, and all unmeasurable quantity’.

The Problem Approach: Brian Holmes

Brian Holmes of the University of London Institute of Education, before Noah and Eckstein, and consistently for several years after them, advocated another ‘scientific’

approach to comparative education, what he called *The Problem Approach*. The main parameters of this approach and Holmes' conception of CE as a field of study may be reconstructed as follows:

- (a) Comparative Education should be conceived and developed as a predictive social science. Drawing from Karl Popper's 'hypothetico-deductive' method – it should be post-relativity social science.
- (b) As such, it should eschew the positivism, determinism, absoluteness, and unconditionality of pre-relativity empirical science, as well as any universality or inexorableness in laws of social development as are to be formed in the 'historicist' analyses of societies (e.g. those of J.S. Mill, Karl Marx and Herbert Spencer).
- (c) Further, post-relativity social science 'espouses relativistic theories of science' which presuppose the specification of problems, the formulation of hypotheses or 'sociological laws', a detailed specification of 'the complete range of determinants', an analysis/description of the initial conditions or the context, upon which the outcome to a solution to the problem will be predicted. In Holmes' own words:

The test of a good theory is its predictive usefulness ... but no theory can be used to predict events unless it is accompanied by a careful analysis and statement of the initial conditions or circumstances likely to affect the predicted event (Holmes, 1958: 247).

- (d) Schematically, Holmes' methodological formula may be reconstructed as follows:

$$L + I = P$$
 where L = Law ("sociological law")
 I = Initial conditions
 and P = Problem
- (e) Predictions, the distinctive feature of scientific comparative education, must be 'tentative' and 'conditional', which differentiates them from 'unconditional' prophesies about the future of education.
- (f) From the perspective of post-relativity social science, 'explanation is provided by the process of prediction and verification'. Within such 'hypothetico-deductive' methodological framework, in contrast to Noah's and Eckstein's, and to other similar hypothetico-inductive frameworks, prediction of a specific event also entails explanation. In Holmes' own words:

Hypothetico-deductive procedures, whether for the purpose of explanation, prediction, or testing, are the same. Indeed the outcomes are not very different either. If a specific event is predicted it is also explained and a general statement has been tested. A theory or hypothesis is verified when predicted events are conformed by actual observations; refuted when predicted and observed events differ (Holmes, 1965:30, 1981: 51).

- (g) Comparative education research must be centred in problems, and must be pragmatic. More than being conceptualised as a 'pure' scientific enterprise, it should be approached as a pragmatic enterprise that aims at the solution of problems. Thus it should develop both as a predictive science and as 'an instrument of reform'. And it should look towards the future not the past (Holmes, 1965: 32).

History, Social Science and Comparative Education: Quest for a Synthesis: A Personal Testament

In the 1960s, during the heyday of the intellectual ferment to chart new methodological trajectories, a distinct minority of the new "advocates" of the reform movement sought to revise the historical approach to CE and bring about a synthesis of the historical and the scientific elements. One of these people was Kazamias, the present writer of this chapter. In the early 1960s, reflecting the intellectual mood of the time, I criticised the traditional historical cum melioristic approach as exemplified by Kandel. But in my efforts to make CE a more systematic and a more theoretical comparative *episteme*, I did not reject the importance of the historical element. I called for a revised historical approach that would combine history with social science. I held that what vitiated the approach of the doyens of comparative education, especially that of Kandel, was not their historical orientation as such, but, among other things, 'their historical propensities, especially their assumptions that history deals with 'unique' and different phenomena which cannot be generalised'. Influenced by a debate that was carried out at the time in academic circles about the nature and methods of history and its similarities, as well as its differences with the social sciences, I argued that a historical approach to the comparative study of education did not necessarily preclude conceptualisation (the use of concepts) and generalisation, or indeed quantification, which were considered basic elements of the scientific paradigms. Commenting on the 'functional-sociological' approach, I argued that it was limited for 'understanding' and 'explaining' educational phenomena. My views regarding the value of history in comparative education were stated in 1963 as follows:

The assertion that history deals essentially with unique and particular events, and that consequently its value for comparative analysis, which presupposes abstraction, generalisation and regularity is questionable, has been refuted by several writers including historians. As Crane Brinton, the comparative historian, has shown, it is quite possible to categorise or classify historical phenomena and compare them for the purpose of making generalisations. Although such generalisations may be of a limited rather than a universal nature, they may in turn be used in working hypotheses to be tested in other similar situations in order to illuminate them. In other words, from an examination of the specific, the concrete and the particular, the historically-minded comparative educator may induce a generalisation and then use it in order to illuminate another particular event or form. The concern for the general and the particular is to be found in both the social sciences and history, and the

difference is one of emphasis and objectives of research rather than kind or method (Kazamias, 1963: 396).

In lively debates in international conferences and in the columns of international journals such as the *Comparative Education Review* and the *International Review of Education*, I criticised the emergent scientific paradigms – the structural-functionalism of the University of Chicago, the positivistic methodologism of Noah and Eckstein, and Psacharopoulos and the problem approach of Brian Holmes – as well as the then much acclaimed IEA international studies. One of his main criticisms was that they were ahistorical.

Conflict Paradigms: Marxist, Neo-Marxist, Weberian and World-Systems

The ‘functionalist’ and the ‘methodological empirical’ versions of CE, as outlined above, held sway until well into the 1970s. But other paradigms, that can also be said to fall under the ‘scientific’ epistemological rubric, were visible during this period; and some of these became more salient in the years that followed. I shall refer to this variety of ‘scientific’ comparative education as ‘conflictual paradigmatic discourse’. Within this generation of comparative discourse, a particularly significant radical genre can be discerned. By ‘radical paradigms’ I mean approaches or theories that view schools as instruments of domination or as ideological apparatuses of the state, that reproduce and perpetuate the hegemonic interests of particular groups; as arenas of imbalanced social conflict; as repressive and inegalitarian institutions; and as places that inculcate ‘monocultural’ ideas, values and attitudes (based on class, race, ethnicity and gender). Therefore, to understand school–society relationships and the role of schooling in, for example, capitalist social formations, one must inquire into the power structure of such modernised societies and into the social relations of production. Or from another conceptual prism, namely, a ‘world-systems’ perspective, to examine comparatively education–societal interrelationships, one must probe into the ‘international’ or ‘world’ context and dynamic of such relationships and transactions. Among other things, a ‘world-systems’ macro type of comparative analysis deviates from others in at least two respects. In the first place, it challenges the commonplace traditional approaches that take the nation state as the exclusive framework of analysis, and by extension, it does not take education ‘as a parochial national institution anywhere in the world’. As Klaus Hufner, John W. Meyer and Jens Nauman in the volume *Comparative Policy, Research: Learning From Experience* (1987: 188–189) put it:

Put simply, education is not a parochial national institution anywhere in the world; it is a rationalized part of the technology of progress and modernisation, and modernisation is a central and world- legitimated goal practically everywhere. This means that education is itself a scientific construction, built not around primordial traditions of society, but around a general technology of resocialising populations to achieve progress. As a world-wide technology, it is built on research and policy comparisons that tend to flow rapidly from one setting to the next.

In the second place, one variant of the 'world systems' comparative education discourse, based on Immanuel Wallerstein's theory of the 'modern world system', not only probes into the 'international' or 'global' context/dimension and dynamics of educational systems; it also perceives such context or dynamic as being of a hierarchical, unequal and exploitative nature existing or taking place within a 'core- or centre-periphery' dependency framework. Robert Arnove, an exponent of this variant of the 'world-systems' comparative analysis, in *Comparative Education* (1982: 454), put it as follows:

Dependency theory basically articulates a descending chain of exploitation from the hegemony of metropolitan countries over peripheral countries to the hegemony of the center of power in a Third World country over its own peripheral areas. Closely related to such notions of center and periphery are the concepts of Wallerstein concerning convergence and divergence in the global system. As summarized by Meyer et al, the world market and society produce convergence by subjecting all societies to the same force; they produce divergence by creating different roles for different societies in the world stratification system.

The intellectual provenance of 'radicalism' in this generation of comparative education discourse may be traced to, among others, conflict theorists (Weberian, Marxist and Neo-Marxists), dependency theorists, and the so-called new sociologists (Kazamias & Massialas, 1982). The distinguishing features of the 'conflict' paradigms *vis-à-vis* the 'functional-equilibrium' paradigms, for example, were well brought out by Rolland Paulston, a leading comparativist who has written extensively on the methodology of comparative education, in the 1977 'State of the Art' issue of the *Comparative Education Review*. There, Paulston identified, among others, such central concepts as *power, exploitation, contradictions, ruling class, control of knowledge and cultural hegemony* (Paulston, 1977: 386). To this conceptual tapestry I later added: *class conflict, social and political inequalities, reproduction, oppression, alienation, imperialism, dependence* and the *capitalist state* (Kazamias, 1991).

Another prominent variant of this radical discourse is best represented by the work of Martin Carnoy, a Chicago-trained economist turned revisionist neo-Marxist comparative political economist of education. Carnoy's reputation as a radical comparative educator, will, in all likelihood, rest on his influential book *Education as Cultural Imperialism* (1974), but, more so in my judgement, it should rest on his state-centred perspective in the comparative study of national systems of education. In one of those recurrent debates on what we have called the *protean* nature of the comparative *episteme*, occasioned by the 1993 presidential address by Erwin Epstein (1983), Martin Carnoy explained his revisionist neo-Marxist state-centred approach which, according to him, differentiated it from the 'positivist' as well as from the more orthodox Marxist and neo-Marxist approaches, as follows:

We are trying to understand what schooling is, how it works, and how it relates to the society in which it functions. Positivists approach these problems from the standpoint of individual choice, because they believe that power is subjective

and the ideal organization of schooling is one in which that subjective (individual) power is allowed to find its full expression. Neo-Marxists generally see schooling as serving an objectively determined set of power relations – in capitalist society, relations that give control over institutions to a ruling capitalist managerial class With that kind of discussion in mind I would like to draw attention to the ongoing neo-Marxist debate on the State . . . unlike conventional neo-Marxist writing, we argue that schools are not simply the tools of capitalists (in capitalist society) but an institution where the tensions among the forces for reproduction (reproduction of the objective relations of production) – which Bowles and Gintis call correspondence – and the forces of democratization (individual and collective expression) – which we call contradiction – are played out. Thus, the schools contain elements of reproduction and democracy, just as the State as a whole in capitalist and state bureaucratic societies contains these elements. Therefore, we do assume that the State in both capitalist and state bureaucratic societies fundamentally reproduces hierarchical and inequitable power relations, but that it and the educational system it uses in reproduction contain important contradictions (Carnoy, 1983).

In a later text, entitled *Education and Social Transformation in the Third World* (1990), where Carnoy and his co-author Joel Samoff engage in an actual comparative inquiry into educational change in Third World ‘transition societies’ (e.g. People’s Republic of China, Cuba, Tanzania, Mozambique and Nicaragua), we are presented with similar ideas. In this, for our purposes here most important text, as in the aforementioned one, Carnoy distances himself from orthodox Marxists and from orthodox neo-Marxists. And, one may add, he distances himself from the Marxist-informed dependency theorists, another contemporary breed of radical comparativists. Focusing on ‘the state and politics’, Carnoy and Samoff seek to ‘analyse whether and why education develops differently in societies that seek to make a transition from capitalism to socialism than in their Third World capitalist counterparts’. Their thesis is stated as follows: ‘It is the state, much more than the production system, we argue, that is the source of the dynamic of revolutionary societies, and *politics, much more than relations in production that drives their social developments*’. Continuing in the same vein, they add: ‘The importance of the state and politics is not limited to the analysis of societies undergoing social transformation. We *also make a case for increasing focus on the state and its relation to the economy in understanding how social structures in Third World capitalist societies remain relatively unchanged*’. According to them, ‘*notions of correspondence, cultural reproduction, and contradiction*’ are important ‘in developing an analysis of education’s role in social transformation’, but they fail to develop a coherent theory of the relations among economy, ideology, and political system (the state) and, in turn, a theory of the relationship between the state and the educational systems. And reasserting what may be referred to as a ‘state-centred’ thesis, they argue that a *theory of the state is even ‘more crucial in understanding present-day transition societies in the process of social transformation, for in them politics is the primary arena in which the transformation is played out’* (Carnoy & Samoff, 1990: 3–9, italics mine).

Reclaiming a Lost Legacy: Reinventing the Historical in Comparative Education

In the 1980s and the 1990s there was a noticeable retrenchment in the institutional expansion of programmes in comparative education. Yet, cross-national educational studies and research, as well as activities that dealt with international education, broadly defined, continued to grow. Comparative and international education showed considerable robustness in terms of membership in professional associations, participation in international conferences and publications in leading journals. Epistemologically and methodologically new paradigms were incorporated into comparative research, such as the feminist critique, and even postmodernity, which in one sense enriched the conceptual tapestry or mosaic that has characterised the field since its aforementioned explosive development in the second half of the twentieth century (Arnové & Torres, 1999; Masemann & Welch, 1997). As the Editor of the *Comparative Education Review* wrote in 1991 about American CE:

Comparative education has changed significantly since the 1970s. Topics that were considered unimportant, such as the role of gender in education, have become the subject of research and analysis. New methodologies, such as ethnography and participant observation, have become important. And alternative ideologies such as Marxism have been used to inform analysis in comparative education. The domination of such paradigms as structural functionalism was broken. It is significant that nothing has emerged to replace these ideas as the primary direction of the field. Rather, a variety of different perspectives have entered into comparative education research.... In many respects, these developments mirror the situation in the social sciences generally (Altbach, 1991: 504).

On the British comparative education landscape, several other differentiating epistemological-cum-methodological characteristics and new orientations are patently visible. First, there is the renewed emphasis on what many years back we had called 'comparative pedagogy', a most important aspect of the process of education, and what Broadfoot has called '*learnology*' of education (Alexander *et al.*, 1999; Broadfoot, 1999). Second, I wish to underline the British traditional and lately reinvented emphasis on *contexts* and *cultures*, both of which figured prominently in the millennium special issue of *Comparative Education*. These two epistemic emphases render the British comparative education more human and humane than the American, and the way of reading the world less mechanistically and economically motivated, a point which I develop elsewhere (Kazamias, 2001). And, lastly, the British comparative education discourse is less prone to intellectual fads and to epistemological-cum-methodological cannibalism as the American.

Epilogue

But such developments, I would argue, were made at an epistemological cum methodological cost, namely, the sacrifice or almost total abandonment of the historical dimension in comparative educational research. According to a recent study, 'research

strategies in comparative education from 1955 to 1994 revealed that only 10.5 per cent of almost 2000 articles in the *International Journal of Educational Development*, *Comparative Education* and *Comparative Education Review* relied on historiography and historical research'. And, even more disappointing: 'From 1985–1995, less than 5 per cent of all articles published were characterized as historical studies' (Larsen, 2001), comparative-historical or historical-comparative. This state of affairs has prompted one commentator to observe that our field suffers from 'historical amnesia' (Larsen, 2001).

PAIDEIA AND POLITEIA: EDUCATION, AND THE POLITY/STATE IN COMPARATIVE EDUCATION

Andreas M. Kazamias

Interest in the political relations of education/*paideia*, particularly in the relationships between education and the polity/*politeia* or the state, has been longstanding in the Western educational and political traditions. It has been especially evident in the texts of influential social thinkers such as Plato, Aristotle, J. J. Rousseau, John Locke, Karl Marx, J. S. Mill, Herbert Spencer, Antonio Gramsci, Louis Althusser, Cornelius Castoriadis, John Dewey and Paulo Freire. In his most famous political treatise, the *Politics (Politika)*, Aristotle, for example, as a ‘comparative political philosopher/scientist’, averred:

Now nobody would dispute that the education/*paideia* of the young requires the special attention of the lawgiver. Indeed, the neglect of this in ‘city-states’ is injurious to the polities; for one ought to be educated [and ‘habituated’] in accordance with the particular form of the polity/*politeia*, for the particular character/*ethos* of each polity both guards the polity generally and originally establishes it—for instance the democratic *ethos* promotes democracy and the oligarchic *ethos* oligarchy; and a better *ethos* always produces a better polity/*politeia*.

Aristotle further emphasised that the *paideia* of the young should be ‘public’ and not ‘private’, since ‘matters of public interest should be under public supervision’ (Aristotle, 1958, Bk. VIII).

In the history of comparative education, the influential older doyens, e.g. Isaac Kandel and Nicholas Hans, considered the ‘political’ as an important dimension, factor or contextual explanatory variable in their historical-philosophical-humanist studies of national systems of education. And as critically analysed by the present writer in the first section of this Handbook, Kandel, in particular, echoed Aristotle in considering the ‘state’ as a determining variable in explaining the character of national systems of education. As Kandel himself had stated: ‘every state has the type of education that it wills’, and “as is the state so is the school’ (Kandel, 1933: 274, 275).

In the post-Kandelian post-Hansian development of comparative education in the 1960s and 1970s, the political perspective that characterised much of the research and writing in comparative education was twofold: (a) the ‘education politics’ perspective,

to use Roger Dale's terminology, and (b) the 'functionalist-modernisation political systems' perspective.

The 'Education Politics' Perspective

Contrasting what he called the 'education politics' and the 'politics of education' perspectives, Dale has noted:

Those political scientists who have focused on education have confined their studies very much to education politics rather than the politics of education. By this I mean that they have concentrated much more on studying the effectiveness of education systems and forms of education government in achieving goals presented to them, rather than on the relationships between the production of goals and the form of their achievement. To put it another way, political questions are bracketed out and replaced by questions about processes of decision-making; politics are reduced to administration; The focus is on the machinery, rather than on what powers it, or how and where it is directed (Dale, 1982: 128–129, underlining mine).

The 'education politics' perspective in comparative education was evident in at least two wide-ranging and quite extensive types of studies. First, there were the many predominantly descriptive and generally non-theoretical works that recounted the powers, duties and responsibilities of the decision-making and policy-making apparatuses of the government, the administration and the control of educational systems. Where efforts were made to typologise patterns of governance and administration, control was often used and comparisons made between 'centralised' and 'decentralised' systems (Litt & Parkinson, 1979). The second type of studies, more theoretical than the first, but still carried out through a similar epistemological prism, included those that conceptualised the education-politics interaction in terms of what may be called an 'interest-group', often a 'pluralist interest-group' theoretical framework or paradigm. Examples of this genre of the 'political' in education abounded in the literature on educational policy-making and reform. In one common variant of the interest group model—the pluralist democratic model—education was conceptualised as a site, an arena of political conflict involving different social interest groups (teacher organisations or unions, political parties, religious groups, business, labour, students, etc.), which vied with each other for power, influence and prestige. Educational reform from this perspective was the outcome of such conflict, either because consensus had been reached or because the views of one group or of a coalition of groups had prevailed. Alternately, reforms were thwarted or failed because in the group struggle the balance of power was tipped in favour of opposing interests (Peterson, 1973; Heidenheimer, 1974; Kazamias, 1978; Thomas, 1983; Lauglo & McLean, 1985).

In a paper presented at the annual meeting of the Comparative and International Education Society held in Washington, DC in March, 1987, I pointed out that inquiries based on the interest group pluralist model, although enlightening conceptually and

sophisticated methodologically, had certain limitations; they did not probe beneath the visible arena of conflict and policy formation into the structural context of the larger national and international society in their search for explanations. Returning to Dale's characterisation, I argued that interest-group pluralist analyses did not engage in the 'politics of education', i.e. into what powers the machinery of the governance of education, or how and where the machinery was directed; that is, their explanations were restricted and their directions were indeterminate (Kazamias, 1987). As with pluralism in general, the pluralist approaches to the political relations of schooling and educational reform have the following inadequacies:

- (a) They assume that 'the structure of power is segmented, not organized into a clear hierarchical pattern', or, to put it in another way, 'power is non-hierarchically and competitively arranged'.
- (b) They provide limited, piecemeal explanations of political power and processes.
- (c) They tend to move toward a functional equilibrium theory.
- (d) They assume that (i) the state is a 'neutral arbiter among social interests', and an 'empty state', and (ii) that all groups have equal access 'to the minimum resources for political mobilization', and compete favourably (Miliband, 1969).
- (e) They tend 'to concentrate group bargaining with a nation-state', without relating the state 'to the context of international conditions and pressures' (Held, 1984: 67–68).
- (f) They are predominantly 'society-centred' in that their conceptualisation of school–society relationships and their explanatory strategies view the state simply as an arena of competition/struggle to gain advantage, or as a 'functional entity' responding to societal 'needs', social imperatives and 'societal strains' (Skocpol, 1979: 29).

The 'Functionalist-Modernisation Political Systems' (FMPS) Perspective

The 'functionalist-modernisation political systems' perspective in comparative education, that was prominent in the 1960s and 1970s, was best exemplified by the influential Princeton series on political culture and political development, sponsored by the Committee on Comparative Politics of the Social Science Research Council. In the comparative education literature, it was best exemplified in the volume entitled *Education and Political Development* (1965) in the same series, and edited by J. S. Coleman.

As with the aforementioned pluralist perspective, analyses of the education-polity relationships from the FMPS perspective were predominantly society-centred. Indeed, the Princeton School of political culture and development eschewed the use of the concept of the 'state' because, according to its spokesmen: (a) it was too restrictive, (b) it was more applicable to Western developed societies, (c) often it was used synonymously with the government, (d) it did not take account of the concept of

political culture, and (e) it would not accommodate the notion of ‘interdependence’ of the various parts of the polity, an essential characteristic of the ‘political systems’ and the functionalist approach. For these reasons, the FMPS Princeton School replaced the ‘state’ with ‘political system’, which was defined as follows:

What we propose is that the political system is that system of interactions to be found in all independent societies which performs the functions of integration and adaptation (both internally and vis-à-vis other societies) by means of the employment, or threat of employment, of more or less legitimate physical compulsion. The political system is the legitimate, order-maintaining or transforming system in the society (Almond & Coleman, 1960: 7).

Referring specifically to the functions of political systems and their relation to education, Coleman wrote: ‘For our purposes ... at least three processes or functions of the political system can be identified which have a fairly clear relationship to education. These are political socialization, political recruitment and political integration’ (Coleman, 1965: 17–18).

Reviewing the extensive work done in these three political relations of education, Massialas in 1977 concluded:

The review indicates that researches have sought to find out, in a systematic way, how the schools affect the development of citizen political attitudes, how the schools function as agents of recruitment into political leadership, and how they contribute to the development of a modern nation. On the first question, i.e., in the formation of political attitudes and knowledge, research indicates that the school, overall, is not as significant as other social agents. The school becomes significant, however, with regard to political recruitment albeit in a fashion that to many is ideologically unacceptable, i.e., it tends to promote the perpetuation of power elites. With regard to the third question, dealing with nation-building, the research indicates that the schools tend to reinforce preexisting social cleavages and inequalities (Massialas, 1977: 294).

Bringing the State Back in Comparative Education

In the 1970s, critical political theorists, political sociologists and other social scientists, in seeking to understand the power structure, the policy formation, the functioning and the dynamics of government of contemporary polities and societies, particularly the economically advanced capitalist and politically liberal democratic nation states, focused their critical enquiries and investigations on the nature, the institutional structure and the mechanisms of government which together make up and shape ‘the state’. Particularly worthy of note during this period was a highly publicised ‘leftist’ debate on the nature, activities and functioning of the liberal capitalist state involving distinguished critical social and political theorists on both sides of the Atlantic: Ralph Miliband (1969) and Perry Anderson (1979) in England; Nicos Poulantzas (1978) in

France; Claus Offe (1973) in Germany; Goran Therborn (1980) in Sweden; and Erik O. Wright (1985) and Martin Carnoy (1984) in the United States.

In the 1980s, the state, in the words of Theda Skocpol (1985), a historical sociologist, was ‘brought back in’ comparative studies of the past in order to find out how societies work and change. Historical sociology, according to D. Smith, ‘is carried out by historians and sociologists who investigate the mutual interpenetration of past and present, events and processes, acting and structuration. They try to marry conceptual clarification, comparative generalization and empirical exploration’ (Smith, 1991: 3).

Taking my cue from Skocpol’s proposal, at about the same time (1987), as a historically oriented comparativist with research interests in the ‘politics of education’ more than in ‘education politics’ – to go back to Dale’s distinction – and the role of education in the development of nation states, I suggested to the community of comparative educationists to ‘bring the state back in comparative education’. Yes, ‘bring the state back in’, but not in the Kandelian conceptualisation and interpretation. At the Washington, DC Conference, mentioned above, I said:

Our conceptualization of the state is quite different from Kandel’s. Kandel’s typology of states into “totalitarian” and “democratic” was too general and ‘simplistic’, as were his criteria for such differentiation, namely (a) the ostensible locus of control, which led Kandel to such general categories as centralized and decentralized; monolithic and dispersed; metaphysical and experiential; authoritarian, autocratic/dictatorial and unjust, and liberal and just; and monopolistic and laissez-faire, and (b) the putative relation of the individual to the state (i.e., in the case of the liberal democratic state, the individual was allowed more freedom, while, for its part, the state seeks to promote the well-being of each of its members (Kazamias, 1987).

I then added that my view of the state was not a hypostatized entity independent of civil society, a concept that is often conjured up in people’s minds perhaps because of the historical and influential German Hegelian idealism. Furthermore, I said the following:

Our concept of the state is not synonymous with the government. Nor is our view of the state system synonymous with Almond and Coleman’s or David Easton’s “political system”... As Stuart Hall explained: “The complex character of the state cannot be reduced to the ways in which the institutional machinery of government functions.” And according to Miliband: “What the state stands for is a number of particular institutions which, together, constitute its reality, and which interact as parts of what may be called the state system”. Institutions include: the government, the administration, the military and the police, the judiciary, units of sub-central government, and parliamentary assemblies (Kazamias, 1987).

On the distinction between the state and the government, I quoted Alfred Stephan who had written:

The state must be considered as more than the “government”. It is the continuous administration, legal, bureaucratic and coercive systems that attempt not only to structure relationships between civil society and public authority in a polity but also to structure many crucial relationships within civil society (Quoted by Skocpol, 1985: 7).

Education, I pointed out in the same forum, is an important function/activity or, as Louis Althusser famously said, an ideological apparatus of the state (Althusser, 1971). I explained:

Today, the public sector in education, which is regulated, controlled or planned by the state accounts for the overwhelming percentage of educational provision from the lowest to the highest levels of the educational system. Even the private sector is subject to state regulation. There is hardly an aspect of the educational system – organisation, administration, curriculum, teacher training, financing, examinations, etc. – that is not directly or indirectly related to the state.

And I concluded:

Given the above, I need not elaborate on the significance of examining education from the perspective of the state. Not from the mainstream perspective, nor from the Kandelian perspective, but from a structural, conflict, relational, ‘state as actor’, and state ‘as relatively autonomous’ perspective. Locating education in the conceptual and epistemological problematic of the state, as previously defined, would allow us not only to ascertain and analyse its workings and social dynamics; it would also go a long way towards providing more complete explanations of educational patterns, policies and reforms, what accounts for similarities and differences among systems, and what conditions have obtained for educational change and reform (Kazamias, 1987).

In the 1990s, the state was indeed brought back in comparative education, and I am pleased to say, not from the ‘mainstream perspective’ nor from that of Kandel. A noteworthy comparative study approached from a revisionist neo-Marxist perspective was Martin Carnoy’s and Joel Samoff’s *Education and Social Transformation in the Third World* (1990). I discuss this book in another chapter in Section One of this Handbook. Suffice to note here that in this state-centred study, Carnoy and Samoff sought ‘to analyze whether and why education develops differently in societies that seek to make a transition from capitalism to socialism than in their Third World capitalist counterparts’. The societies studied were: the People’s Republic of China, Cuba, Tanzania, Mozambique and Nicaragua. The authors’ thesis was that it was the state, much more than the production system that was ‘the source of the dynamic of revolutionary societies and politics, much more than relations in production that drove their social developments’ (Carnoy & Samoff, 1990).

Other examples of noteworthy studies that appeared in the 1990s on the education-polity nexus were Green’s *Education and state formation: The rise of education systems in England, France and the USA* (1990) and C. A. Torres’s *Democracy, education and multiculturalism: Dilemmas of citizenship in a global world* (1998). Green’s path-breaking comparative historical-sociological study examined the role of education in the process of state formation and nation-building in three modern Western liberal democracies (England, France and the USA): how education as a state mechanism

acted to cultivate social cohesion, citizenship, national culture and national identity as well as to train personnel for the civil bureaucracy and the apparatuses of government at the national and local levels (Green, 1990). In a lengthy chapter on ‘The State and Education’, Torres first grapples with problems of defining ‘the State’ and with the significance of a state – centred approach to the study of educational policies and practices, or ‘the connections between citizenship, democracy and multiculturalism’ (Torres, 1998:14). In subsequent subsections he examines from a critical theoretical perspective (a) classical theories of the state from ‘Liberalism’ to ‘Marxism’ and education, (b) the contemporary ‘neoconservative’ and ‘neoliberal’ states and education, (c) ‘neo-marxist theories of the state and the critique of neoconservatism and neoliberalism’, (d) ‘postmodern perspectives on the state and education’, and (e) ‘against the patriarchal state? feminism and the color of the state’ (Torres, 1998:26–69).

Epilogue

The significance of engaging in state-centred comparative educational research today, despite the talk about the shrinking role of the state, was underscored quite recently by Martin Carnoy in his Presidential address to the Comparative and International Education Society in 2006. Carnoy explained the reasons for engaging in such research:

First, most education in most countries is provided by the state. Second, even when education is partly “private” and partly “public”, it is the state that defines the meaning of public and private education. In most countries private school teachers are paid by the state. Third, because the state is the supplier and definer of education, the way changes take place in educational systems is largely defined by the political leadership of the nation’s citizenry to the state and the way that the state has organized the educational system politically (Carnoy, 2006: 555).

To these reasons, one could add that education is still an important mechanism in the formation of states and in nation-building in many countries of the world; and, lastly, to paraphrase Aristotle as quoted in the beginning of this chapter, ‘one’s *paideia* (education) ought to be in accordance with one’s *politeia* (the state)’.

EMPIRES AND EDUCATION: THE BRITISH EMPIRE

Gary McCulloch

This chapter analyses the interactions involved in the relationship between Empires and education by exploring the case of the British Empire. Over the past few years, increasing attention has been given to the history of the British Empire and the nature of its contribution and legacy in the modern world (Louis, 1999; Ferguson, 2003; Brendon, 2007). Much of this general literature, for example, the recent five-volume *Oxford History of the British Empire* (Louis, 1999), has included little material specifically on education. At the same time, a substantial literature has also developed on the ways in which the ideas and practices of education in Britain influenced the character of education in different parts of the British Empire. This literature has generated interesting debates around the nature of cultural imperialism, the relationship between the ‘centre’ and the ‘periphery’ (e.g. McCulloch & Lowe, 2003), the extent to which imperial influences were beneficial and the ways in which these influences were played out in different nations and areas. Latterly, there has been increasing interest in the kinds of resistance that developed on the part of colonised and indigenous groups. The case of New Zealand (Maori name Aotearoa), 12,000 miles away from Britain, will be examined in particular detail to demonstrate the extent and the characteristics of the imperial writ.

Yet the educational relationships between Britain and her Empire did not run only in one direction. As Peter Burke has pointed out, there are evident dangers in a simple model of ‘centre’ and ‘periphery’ in which knowledge is diffused from Europe to other parts of the globe, in particular for the tendency of such an approach to take sufficient account of ‘flows of knowledge from periphery to centre as well as in the opposite direction’ (Burke, 2000: 57). Over the last decade, there have developed the beginnings of historical interest in the reverse process, that is, how ideas and practices of education in different parts of the British Empire exerted influence in the imperial homeland. This new literature, stimulated in part by Edward Said’s *Culture and Imperialism* (1994), has potential for a great deal of further development to investigate the dynamics of education in the British Empire which were rarely stable and often unpredictable in their nature and effects.

English Education and the British Empire

What J.A. Mangan described as the ‘imperial diffusion’ of British education (Mangan, 1978: 110) around the British Empire from the nineteenth century onwards has become a familiar feature of educational historiography. More specifically, as Mangan’s work

among many others has demonstrated, English traditions were dominant in this process, and differed significantly from those of Scotland, Wales and Ireland. These latter traditions tended to be subordinated to the English while still retaining local support and potency (Raftery et al., 2007). Mangan's own research emphasised the ways in which the great independent or 'public' schools of England established the ideals that were to become dominant in many different social and cultural contexts around the world, and also the active involvement of the products of these schools in proselytising and implementing them in the British colonies. The universities were also to the fore in advancing the imperial theme, in particular Oxford with the strong encouragement of men such as Benjamin Jowitt, Master of Balliol from 1870 to 1893. Other Oxford men who pursued the dream of cultivating the English tradition in the colonies were to include Sir Cyril Norwood, Master of St. John's College from 1934 until 1946. Yet it has also become clear that these powerful influences did not hold sway unchallenged. In a number of colonies, local conditions led to significant variations, adaptations and often active resistance to the imperial blueprint.

The public schools created an identifiable elite, a community of men with shared outlooks, values and codes of honour imbued in them through their shared boyhood experiences. They were indeed a breed of 'philosopher-kings' in the Platonic model, prepared for public service and the running of an Empire (Wilkinson, 1964; Honey, 1977; McCulloch, 1991a). They inculcated high ideals of Christianity and liberal education, as well as a rugged brand of moral character and patriotism. By the end of the nineteenth century, the ideals and practices of the public schools could be widely portrayed as representing an English tradition, legitimising status and relations of established authority.

Mangan's work in the 1980s and 1990s made a significant contribution to the understanding of this quintessentially English version of cultural imperialism. His key work *The Games Ethic and Imperialism* (1986) examined in extensive detail the significance of games and sports in the education of the Empire. The 'games ethic' lay at the heart of the values disseminated by the public schools, imparting not only initiative and self-reliance but also loyalty and obedience. Public school headmasters in the late nineteenth and early twentieth centuries actively supported imperial ideals, and sent their pupils to the furthest outposts of the Empire to put them into practice. In this way, according to Mangan, 'a unique educational ideal was disseminated throughout the British Empire – the ideal of character-training through games' (Mangan, 1986: 42; see also Mangan, 1988, 1993). Rugby football and cricket in particular were the chosen instruments of imperial purpose. In Sudan, for example, the Sudan Political Service, created in 1899, drew copiously on the products of the English public schools and of the universities of Oxford and Cambridge to form an elite cadre of administrators. Many of these had themselves achieved sporting success in their former schools and universities, and strove to pass on the values underlying their achievements to their new charges. In Nigeria, Sir Frederick Lugard led an educational crusade in his position as Governor from 1912 (Governor-General from 1914), preaching the virtues of conformity and obedience both in the classroom and on the playing field. In India, Mayo College, founded in 1878, was a notable example of a new school based on the precepts of the English public schools, which spread the word through the development of cricket and other games.

Further detailed accounts of the educational sources of this set of imperial influences developed this general theme. Donald Leinster-Mackay noted the significance of the English preparatory schools as the ‘cradle and crèche of Empire’ with their close associations with the public schools (Leinster-Mackay, 1988). Paul Rich delved into the contribution of public school freemasonry to the cultural hegemony of the British throughout the Empire, involving the development of rites and rituals in the gentleman’s clubs and Masonic lodges (Rich, 1988, 1989, 1991). The textbooks used as part of the curriculum both in Britain and around the Empire also attracted increasing attention, to understand the messages and stereotypes that they conveyed to pupils. Racial stereotypes, for example, were widely depicted in school history and geography textbooks (Marsden, 1990; Castle, 1993; Lilly, 1993; Coolahan, 1993).

The University of Oxford established connections with the British Empire that were especially significant, as was evident from Richard Symonds’ detailed study (1986). This work investigated Oxford’s contribution to the philosophy of and national attitudes towards Empire, particularly through its teaching of the classics. It also examined the purposes and motives behind support for the Empire, and the role of Oxford graduates who went out to different parts of the Empire as administrators, teachers and missionaries. A famous example of an Oxford graduate who set out to colonise the world was Cecil Rhodes, who studied Latin, Greek, Political Economy and Law at Oriel College between 1873 and 1881. Rhodes’ Will, published in 1902, became the basis for the Rhodes Scholarships which appointed thousands of Scholars from all over the Empire in subsequent decades.

Cyril Norwood was a prominent educator who also had roots in Oxford, having attained a First in classics at St. John’s College in the 1890s before becoming headmaster of Bristol Grammar School, Master of Marlborough College and then Head of Harrow School, finally returning to his old Oxford college as President in 1934 (McCulloch, 2007a). Norwood was influenced by his father Samuel, the ultimately unsuccessful headmaster of Whalley Grammar School, who waxed lyrical on the benefits of Britain’s Indian Empire. As the headmaster of Bristol Grammar School before the First World War, he emphasised the duties and the inherited ideals of the British Empire, and the need to defend these if necessary through resort to arms. Later in his career, Norwood identified and celebrated an English tradition of education that was associated above all with the qualities of character found in the English public schools, including the shared values inculcated by games (Norwood, 1929).

There has been much controversy over whether the influence of the British Empire has been malevolent or beneficial. Recent sympathisers have insisted that the Empire had a positive role in the making of the modern world (Ferguson, 2003). Such admiration is evident in some of the historical literature on the British Empire and education. Clive Whitehead in particular has defended the record of the British Empire, and rejected the idea that it was a means of exerting economic and political control over colonised peoples. Whitehead emphasises both the idealism and the confusion of purpose that underlay British colonial policy, and insists that this did not amount to cultural imperialism designed to perpetuate cultural and political hegemony: ‘Most colonial schooling certainly mirrored schooling in Britain, but there is ample evidence

to suggest that this was more a reflection of local demand on the part of indigenous peoples themselves, than an indication of any deliberate British policy to colonise the indigenous intellect' (Whitehead, 1988: 215). Whitehead's research on the British Indian and Colonial Education Service exemplifies this argument as he highlights the contributions of many men and women to building and maintaining public facilities and services in India, based as he argues on 'a genuine concern for the welfare of indigenous peoples' (Whitehead, 2003: p. xiv).

Yet it is also true that tensions developed in a number of colonial contexts over the character and effects of these imperial influences. In some parts of the Empire, these conflicts grew into open challenge and resistance on the part of colonial and indigenous groups seeking a greater measure of independence, or an assertion of national or local character. In relation to India, for example, the British mission schools according to Allender failed to recruit a clientele beyond their central city schools into the rural areas despite expensive programmes of evangelism and conversion in the mid nineteenth century (Allender, 2003: 273). They remained the preserve of the wealthy few, and had little impact on the general population. Instead, rival nationalist and religious movements took the initiative to extend their educational influence before the end of the nineteenth century (Allender, 2003: 288; see also Allender, 2007).

Other British colonies also experienced such educational differences and conflicts. In colonial Fiji, White argues that the educational and 'native' policies of the colonial government helped to encourage uneven educational development and lower Fijian educational attainment (White, 2003). Meanwhile, Swaziland in south-eastern Africa, a British protectorate after the Boer War at the start of the twentieth century, experienced tensions not only between the colonial power and the colonised, but also within those colonised populations (Zoller, 2003). We may observe such tensions in more detail in the historical development of one particular British colony 12,000 miles away from the Homeland: New Zealand.

Educating New Zealand?

The essentially colonial characteristics of education in New Zealand have long attracted comment. The growth of modern schooling in Britain and the dissemination of its educational ideals and practices had a crucial impact on the character of structures of schooling in New Zealand, the furthest outpost of the Empire that continued into the twentieth century. The precedents of established institutions, the practices of schools and teachers, and the traditions that underpinned and rationalised a wide variety of educational arrangements all had their sources in full or in part in what was widely regarded as 'Home'.

Such ideals and practices were continued or else adapted in subtle ways by teachers who themselves had in many cases been educated and trained in Britain, with textbooks that often came from Britain, for examinations based largely on British experience, values and culture. A.E. Campbell, later Director-General of Education, suggested in 1941 that 'the education system of New Zealand as it stands today is incomprehensible unless one bears ever in mind that it originated and developed in a British colony in the nineteenth century' (Campbell, 1941: p. 1). He emphasised the nostalgia of the

colonists for their homeland which contributed to their desire to surround themselves 'with a barrier of familiar social institutions':

If they could not surround themselves immediately with the flowers and trees and quiet hills of England, they could at least transplant the forms of social life with which they were familiar, and which they needed to assuage the homesickness that almost every colonist carries with him to the end. Just because they sought new worlds they did not necessarily seek a new way of life (Campbell, 1941: 3).

For this reason, Campbell concluded, 'the historical principle of maintaining cultural continuity played a greater part in forming the education system of New Zealand than did the geographical principle of adaptation to a new environment' (Campbell, 1941: 6). Auckland Grammar School, for example, imitated and interpreted the practices and ideals of the English public and grammar schools to cultivate its own grammar school tradition. The reflected glow of such schools was intended to convey a cultural message to the pupils and patrons of Auckland: that it was a symbolic link with 'Home' (McCulloch, 1988). The school curriculum no less than the visible structures of the education system also saw unmistakable marks of the colonial heritage. Alan Mulgan, a pupil at Auckland Grammar School in the 1890s, commented looking back that 'Our curriculum was English, but we were colonials and conscious of it' (Mulgan, 1958: 71).

Often, too, there was an idealised and somewhat unreal quality about the images of England that were influential in New Zealand education. For example, F.B. Malim, visiting New Zealand in the 1940s, enthused over the English features of the leading independent schools. Of Christ's College, in Christchurch, Malim remarked that 'Her grey walls and her elms suggest a civilisation more peaceful and stable than seems likely to be the portion of the New Zealand of today, and they remind us of an England with foundations still unshaken by the invention of the internal combustion engine' (Malim, 1948: 160). Malim's observations also highlighted something of the missionary zeal with which English educators had transported their own cultural baggage. He was especially glowing about Waitaki High School, which he described as 'a museum devoted to the history of Britain' (Malim, 1948: 163).

At the same time, there were many important specificities and differences in the New Zealand situation that cannot be merely 'read off' from the British case. It may be argued, indeed, that educational reforms developed in New Zealand in many instances in explicit opposition to the trends identified as being associated with the 'Old Country'. New Zealand educational reforms had a liberal and egalitarian thrust that could be contrasted with the class-based, differentiated and hierarchical structures of schooling in England. It was common for those extolling the virtues of education in New Zealand to emphasise its advantages over that of class-divided England. According to the Director of Education, T.B. Strong, in 1928, for example:

I am told that the teaching profession in England suffers even to the present day the humiliating effects of the old-time perfunctory provision for the education of the masses. There are still localities in England where the teacher has little or no social standing. In the Dominions, fortunately, the trend has been for the teacher

to occupy an honoured position in society, and this fact has undoubtedly operated to the benefit of the schools. One cause, or it may be the effect of this, is the high social regard in which our “public schools” are held (Strong, 1928: 145).

Meanwhile, conservatives such as E.M. Blaiklock, a classics professor at the University of Auckland (Shaw, 1986), tended to paint the ingrained social purposes and structural differentiation of the English education system in more flattering colours to provide a respectable source of right-wing opinion, and to discredit the egalitarianism towards which New Zealand educational policies tended to lean (McCulloch, 1988, 1991b).

In some ways, the egalitarian tendencies prominent in New Zealand education were akin to those of Scotland, which had also developed partly in opposition to English traditions and precepts. As Robert Anderson has noted, there was an ‘advanced and distinctive educational tradition’ in Scotland that could be traced back to the Reformation, which nineteenth-century Scots considered to be ‘both a point of superiority over England and a guarantee of Scotland’s social and cultural autonomy within the Union’ (Anderson, 1983: 1). According to Anderson, the Scottish ‘democratic myth’ of education became a vital part ‘both of the Scottish sense of nationhood and of the image which others have formed of the Scots’ (Anderson, 1983: 1). Underlying the ‘myth’ there were many unresolved problems and deep-seated inequalities that usually went unacknowledged (Humes & Paterson, 1983; Raftery et al., 2007). English-based structures and expectations also increasingly encroached upon educational institutions north of the border to undermine the distinctive character and independence of the Scottish tradition. In New Zealand, the threat of such encroachment was more distant and yet at the same time more insidious. The English cultural origins of the New Zealand education system and its continued influence through the importation of the latest ideas, practices, teachers and texts posed a constant threat to the integrity of New Zealand’s egalitarian myth.

Thus it was a Scottish visitor, Dr. William Boyd, who warned most clearly of the dangers of the English influence at a major conference of the New Education Fellowship held in New Zealand in July 1937. Relating the development of the education system in New Zealand explicitly to that of Scotland, he argued that the key problem facing New Zealand education was the influence of the English tradition, which had already had a major impact at a structural level. According to Boyd, ‘the serpent in the garden is the English influence in New Zealand education which has demoralised your institutions’ (Boyd, 1938: 475–476). Rather than developing along ‘good Scotch lines’, Boyd continued, New Zealand education was based on ‘the English separation between primary and secondary education’. This in turn encouraged differentiation and selection at the secondary school level: ‘Your high schools, rather of the English sort, were meant for an aristocracy, a selected group, and the old primary schools for the common or ordinary people. This is the English principle as opposed to the Scotch practice of having a primary system which grows into a secondary system and forms a satisfactory unity’ (Boyd, 1938: 476). This constituted a direct critique of the views of Cyril Norwood, who was a speaker at the same conference and continued to promote an idealised ‘English tradition’ of education (Norwood, 1929; McCulloch, 2007a). To address this issue, Boyd strongly advocated that the secondary school curriculum should become less ‘orientated towards the university’ and more a ‘preparation for ordinary living’ (Boyd, 1938: 484).

A further key dimension of cultural tensions in colonial New Zealand lay in the relationship between the colonists (*pakehas*) and the indigenous Maori population, the *tangata whenua* or ‘people of the land’. Judith Nathan has argued that the Governor of New Zealand, Sir George Grey, established industrial boarding schools under the Education Ordinance of 1847 in order to consolidate Christianity, foster Western standards, maintain racial harmony, and provide instruments of assimilation (Nathan, 1973). The Maori Schools Act of 1867 established a national system of secular village day schools under the Department of Native Affairs, with a curriculum based on the subjects of English elementary schools (Harker & McConnochie, 1985; Simon, 1998). By the late twentieth century, however, Maori-based resistance to assimilation had grown to the point that it was able to establish alternative and rival forms of educational institutions (Jesson, 1992; Smith, 1992).

This case-study of Aotearoa/New Zealand demonstrates that while the imperial heritage exerted a vital influence on the development of schooling and education more generally, the colonial outpost also developed a number of characteristics that challenged the primacy of these cultural origins. First, the colonists increasingly asserted their own national traditions and national identity in a way that was suited to the conditions of their new home, and which did not necessarily accommodate the precepts and practices of ‘Home’. Second, there were rival international influences such as the distinct values of Scottish education from those of the English, and increasingly other sources of educational ideas and practices such as those of the United States and Australia, with which to contend. Finally, the indigenous culture of the Maori posed particular challenges and suggested important differences in approach in catering for the educational needs of different ethnic groups. Such tensions played themselves out in a number of ways around the British Empire, and the legacies of the British presence were not always similar, but the complexities of the debates experienced in New Zealand had parallels and resonances with those that developed elsewhere.

Small Island

Unlike historical literature on the outward influence of British educational ideas and practices on the different parts of the British Empire, historical attention on the reverse processes by which the Empire has influenced education in Britain has until recently been somewhat scant. A leading writer on this latter theme has been John MacKenzie, whose interest has been directed toward popular culture more generally, but there is much more to be developed in this direction specifically around the character and effects of education.

Said’s work considers the ‘overlapping territories’ and ‘intertwined histories’ of imperial culture (Said, 1994: 1), examining how ‘a post-imperial intellectual attitude might expand the overlapping community between metropolitan and formerly colonised societies’ (Said, 1994: 19). He goes on to investigate how images of the Empire have permeated Western culture, for example in major works of fiction: ‘Cultural texts imported the foreign into Europe in ways that very clearly bear the mark of the imperial enterprise, of explorers and ethnographers, geologists and geographers, merchants

and soldiers' (Said, 1994: 229). This key insight has underpinned a new historical literature focusing on the influence of Empire on the imperial homeland.

Early indications of this new interest have included interesting contributions by the historians Raphael Samuel and Linda Colley. Samuel's *Island Stories* (Samuel, 1998) insists on the interplay of the imperial and the domestic, citing as an example the utopian strains of English life, reflected in the open-air movement and the rise of the Boy Scouts and the Girl Guides in the twentieth century, which were located originally in Britain's colonising fortunes. Colley emphasises the insecurity of Britain in relation to powerful neighbours and rivals as a key factor in its social and political development. According to Colley, 'Self-consciously small, increasingly rich, and confronted with European enemies that were often bigger and militarily more formidable than themselves, the British were frequently on edge, constantly fearful themselves of being invaded, necessarily alert and ready for a fight' (Colley, 2002: 11). The consequence of this in Colley's view was that the Empire came to dominate Britain's culture and self-image (Colley, 2002: 326). Like Samuel, then, she regards Britain's domestic culture and politics and the growth and development of its Empire as being interlinked: 'The history of Britain and the histories of its various overseas ventures cannot be adequately approached separately. For good, and for ill, they were interlinked' (Colley, 2002: 305). Such points are open to debate. For instance, many historians and commentators have suggested that Britain's perceived security from invasion from overseas encouraged complacency and conservatism, rather than restlessness, in its social development (McCulloch, 2007b). However, these arguments provide a point of departure for detailed historical research in a number of different areas.

A number of other recent works have further developed a new historical literature around this theme. In relation to politics, a key example would include Thompson's *The Empire Strikes Back?* (Thompson, 2005), which has explored the role of Empire in British politics in the nineteenth and twentieth centuries. Cultural dimensions have been explored in greater depth by Paris (2000) and Porter (2004). Bush has also assessed the significance of Empire for gender relationships in the early twentieth century (Bush, 2000). The result is what Wilson (2004) has described as a 'new imperial history', actively conscious of the relationship between the British Empire and Britain's own national identity.

The implications of this new historiographical trend for education have thus far been traced out only lightly and unevenly. John MacKenzie led the way in this area as long ago as the 1980s with his study of propaganda, public opinion and Empire and an important edited collection on imperialism and popular culture (MacKenzie, 1984, 1986), and he has continued in this vein (see for example MacKenzie, 1999a, b). These contributions have highlighted how the Empire impressed itself on the British public through such media as the cinema, the popular press, consumer propaganda and popular literature. He singles out the Empire Exhibitions of the 1920s as exemplars of this kind of influence. The first, at Wembley in London, opened by King George V on St. George's Day in 1924, attracted over 17 million visitors during the rest of 1924 and nearly 10 million the following year (MacKenzie, 1999b: 214–215). Its impact on popular awareness and construction of Empire is also vividly depicted in Andrea Levy's recent novel *Small Island* (Levy, 2004) which recounts a visit to the Exhibition by the main narrator Queenie and

her family: ‘the whole world and only one day to see it’ (Levy, 2004: 3–4). MacKenzie points out the significance of social class, the differences between the regional and urban centres of Britain, and the new immigration from the former Empire since the 1950s as factors in the reception of Empire in the twentieth century. These aspects are still to be developed in detail by educational historians, although there is some interesting and important work for example by Castle and Heathorn on national identity and the elementary school curriculum (Castle, 1996; Heathorn, 2000).

Conclusions

We may therefore point to two general types of historical approach to the British Empire and education. The first, well-rehearsed but by no means played out, has investigated the significance of the British Empire for the development of education in its many colonies around the world. This was based on a peculiarly English version of cultural imperialism but was often reinterpreted and challenged in a range of ways in different local, national and regional conditions. The effects have lasted in many societies well after independence and the end of the British Empire itself, reflected in the continued strength and cultural authority of particular institutions and types of curriculum and practice.

The second, developed more recently, pursues the impact of the Empire on Britain itself. This involves the ways in which ideas and practices developed in different parts of the Empire have come to have an influence in the educational system and broader culture and politics of Britain over the past two centuries. This latter type of work is still only in its infancy so far as education is concerned, and it is to be expected that much more will be developed in this respect over the next decade. Again, it is of great potential significance for an understanding not only of historical changes but of outstanding issues in the early twenty-first century. Debates about national identity and ‘Britishness’ are bound up with the continuing impact of the Empire on public debate in Britain (see for example Bunting, 2007). Knowledge and culture have clearly flowed from the ‘periphery’ to the ‘centre’ as well as in the opposite direction.

COMPARING COLONIAL EDUCATION DISCOURSES IN THE FRENCH AND PORTUGUESE AFRICAN EMPIRES: AN ESSAY ON HYBRIDIZATION

Ana Isabel Madeira

Colonial Discourse Analysis

For different reasons, the idealized discourses and the official versions about colonial education in the African context clash with the local circumstances of government forcing the revision, sometimes the subversion, of principles and objectives defined by the metropolitan governments. Very often we realize that the same ‘author’ interprets the reality he observes according to the statute and the locale from where he speaks and acts, frequently making use of arguments of a total opposite signal.¹ Following what Michel Foucault called ‘the *governmentalisation* of the State’ to *govern at a distance*² implies the invention and the construction of a vast set of technologies which link calculations and strategies developed in the political centres thousands of points distributed in the space.³ As such, the analysis of the discourse is linked to the superposition of discourses produced at the global level with the discourses produced at the local level, a process through which the relations of *power–knowledge* are developed in parallel to the technologies of *government at a distance*. These discontinuities in the *scripts* of educational *governance* (Meyer *et al.*, 1997) permit us to understand the coexistence of cultural references and clear political positions, even opposite, in the lusophone (and francophone) space. They underline, on the other hand, the importance of the networks of global diffusion (Ramirez & Rubinson, 1979; Ramírez & Boli, 1987) and of a specific reception, of internationalization and of indigenization, of supranational integration and of intra-national diversification (Schriewer, 1993). This sharing, as I did demonstrate elsewhere (Madeira, 2005 and 2006), results in totally different appropriations, sometimes even opposed, from presuppositions inscribed in the discourse about education, making clear how the discourse productions are used to legitimize the practices of inscription and domination destined to the populations and cultural contexts with characteristics very different among them.

This essay proposes to go beyond a ‘traditional’ vision of educational change, i.e. a concept based on the analysis of influences, forces or relations of cause–effect about the political aspect of education (Wolf, 1982; Murray & Postlethwaite, 1983; Wesseling, 1991). In contrast with the perspectives which consider the colonies as

homogeneous cultural identities, as extensions of the metropolitan ideas and practices, I tend to emphasize the symbiotic relations which developed between the empires and the metropolis (Said, 1993; Cooper, 1994; Thomas, 1994). This position contradicts a representation of colonialism as a coherent and consistent process and defines the colonial scenario as a context of conflict between colonizer and colonized, in which the ideas and practices about the processes associated with the civilization of Africans are open to negotiation and restructuring of a different kind (Kumar, 1991; Thomas, 1994; Bhabha, 1997; Cooper & Stoler, 1999). Therefore the approach that I will sketch here emphasizes the contradictory and conflicting aspects contained in the colonial discourse (Thomas, 1994; Stoler & Cooper, 1997). This implies in particular an understanding about the political and cultural relationship which was developed among the colonies and the metropolis and, within this perspective, exploits it from the configuration of the discourse field about education considering that it limits a historical space in a set of other mechanisms that crossed the colonial space.

This methodological choice is tried and aims at exploring two possibilities which have been of interest to the scientific community within the frame of historical-comparative research in education: on the one hand, to analyse the lack of continuities between the official ideological concepts about education (incorporated in the discourses which originated in the metropolis or even locally) and the strategies of school expansion put in practice in the colonial contexts; on the other hand, to map the circulation of discourses about education at the level of colonial peripheries, highlighting the processes of transfer and of selective taking up which go across the colonies themselves (Nóvoa *et al.*, 2002; Schriewer & Keiner, 1992; Schriewer, 2006; Popkewitz, 2005; Steiner-Khamsi, 2004; Madeira, 2006).

As such, to look at educational changes from a comparative perspective means to analyse how the discourses about colonial education became known and circulated, at the transnational level, and also to understand how these discourses became accepted as a norm and therefore transformed in local strategies and concrete programmes of action. In that sense it is easy to understand why discourses about education which crossed the colonial space produced internal disparities relatively to the processes of school expansion, to the pedagogical models and to curriculum organization, contradicting the concept of educational policy as the local implementation of programmes produced in the European metropolis.

I believe that, from this theoretically defined place, we are able to question other types of relations between the colonial administration and the central structures of power, as well as to question ambiguities and ambivalences which went across the different structures of imperial authority, namely the discourses about the government, the civilization and the education of the colonized (Slemon & Tiffin, 1989).

‘National’ Types, Systems of Government and Comparison of Educational Policies

L'autre est la raison d'être de l'Éducation Comparée: l'*autre* qui sert de modèle ou de référence, qui légitime des actions ou qui impose des silences, que l'on imite ou que l'on colonise. L'éducation comparée fait partie d'un champ de pouvoirs

au sein duquel s'organisent des centres et des périphéries, se construisent des pratiques discursives qui consacrent des *sens* et définissent des *limites* . . . Notre attitude intellectuelle subit l'influence du rôle joué par l'Europe (l'Occident) en tant que référent silencieux de toutes les histoires. Comme si l'Europe était la seule catégorie théoriquement connaissable, toutes les autres histoires n'ayant droit qu'à un statut empirique. (Nóvoa, 1998: 51–52)

The characterization of educational policies through the identification of differences and similarities of the colonial administrative systems implemented by France and England in Africa is widely documented in the literature which compares the governments of the two European powers (Bets, 1961; Deschamps, 1963; Crowder, 1964; Clignet & Foster, 1964; Ipaye, 1969). These descriptions, generally originated in the metropolis and frequently supported in official reports and in speeches of political propaganda, tend to oppose the French colonial system, essentially bureaucratic, centralized and assimilating to the English system, which was considered more pragmatic, decentralized and liberal. The differences between these two ideal types would have originated in the 'historical' characteristics and in the 'political' culture of the two nations. One is republican, even Jacobine, based on a humanism defined by theoretical and abstract principles, thus resulting in a universalistic, unifying and egalitarian tendency. The other, embedded in a political culture more 'aristocratic', inspired on a liberal conservative and in the *laissez-faire* doctrine, would rather tend to respect the position and the culture of local authorities, considered to a certain extent as 'peers' according to the noble tradition of the English gentry – attitudes which supposedly favour the practice of a kind of 'indirect government'.

Another series of myths were associated to the construction of a polarized image of the French and English political systems: for example, the one that argued that the French implemented a colonization system without doctrine and method, in contrast to the British colonization (and decolonization) process, based from its onset on the preparation for 'self-government'; the persistence of direct government methods, based on the principles of domination–subordination, on the French system, in contrast to the autonomy the English gave to the Africans, in relation to meeting the needs and the 'welfare' of the indigenous populations. This set of representations would have re-enforced the idea according to which the French cultural policy tended, especially, to administrative uniformity, unification between the metropolitan territories and those from overseas, tending therefore to the construction of an educational system aiming at assimilating the Africans to the French culture, or at least, submitting the interests of the indigenous people to the civilizing mission of the mother-Nation. In summary, France would have set up the training of a local elite cultivated according to the French moral values and cultural habits, a process which could be considered based on the 'assimilation' doctrine. Regarding England, the discourse about colonial policy tended to present a representation based on opposing principles, based on the adaptation to the local conditions and on the respect for the native indigenous authorities – the 'indirect rule' – implying in a truly decentralizing policy aimed at training the Africans for 'self-government'.

It is not difficult to imagine that, similarly to the 'national' and governmental types, the comparative styles also tended to reproduce the sets of evidence which the

historiography of European colonization in Africa crystallized around the opposition between the francophone and Anglo-Saxon ‘systems’, thus making it possible to describe the educational results met by both nations. The construction of representations, based on the principle of complementarity between the *art and the science of government*, subordinated to political interests of a supranational nature, aimed at very often illustrating the ‘good government’ of the colonized populations. In fact, despite the ruptures of paradigms implemented by British and French critical anthropology and sociology during the 1960s and 1970s, the reading of the colonial phenomenon went on, in recent times, to inspire stereotyped representations of these deliberately radicalized representations:

British Europeanizers . . . hoped to turn their subjects into black Englishmen, complete with middle-class standards and Methodist morality. French Europeanizers . . . hoped to transform tribesmen in French-speaking citizens of the ‘republic one and invisible’. Portuguese Europeanizers dreamed of their country’s Lusitanian mission and envisaged their future empire as an overseas extension of Portugal with a special pattern resembling Brazil’s. (Gann & Duignam, 1971: 216)

The analyses of the governor’s reports, of the local administration and of private groups, for example, constitute a fundamental basis of work for the dismantling of this stereotyped perspective, exclusively centred on official documents, with permits to mix up the similarities and relativize – or re-enforce – the differences, underlying the contradictions of the discourses about education in a colonial context. On the other hand, to work on discourses about education originated in different spaces and times (the colonial space of France and Portugal) makes it possible to widen up the table of comparison centred in the unit state-nation for the vast dimension of the colonial empires. By enlarging the scope of comparison, analysing these discourses as configurations allows us to analyse the diffusion, transformation and appropriation of concepts and pedagogical models as well as their transformation in technologies of educational incorporation (models of teaching, school, and curriculum) within the frame of networks of knowledge.

The Educational Rhetoric and the Construction of the Empire: Portugal and France

Portugal

The system of Portuguese colonization in Africa, based, from a doctrinaire point of view, on the basic principles of international liberalism, whose general characteristics entered Portugal via the double French and English influences, was set essentially on the historical mission and on the colonial vocation which justified the historical, geographic and political imperative of our stay in the continent. Emphatic and somehow messianic, this discourse went through the political cycles and the transitions of

the regime, with few changes, from the end of the monarchy up to the implementation of the 'Estado Novo'. Centred on the civilizing mission, on the nationalization of the empire and, later, on its 'portugalization', the Portuguese colonial idea aimed at the construction of a link between the colonial unity and the national identity, to justify the national grandeur, relatively to the internal public opinion as well as externally in relation to other potential European colonies. In this aspect the Portuguese colonial policy was clearly inscribed in the dynamics of international agreements which regulated the association of the 'right to exploitation' to the 'right of civilization', an argument which presupposed the sharing of a set of principles, transversal to several colonizing powers.⁴ Based on this doctrine, the Portuguese colonial endeavour in terms of education by the end of the nineteenth century and the beginning of the twentieth century was oriented mainly by the principle of the 'assimilation to the national culture', although it distinguished, in practice, the 'civilized' population (the white colonial population, Portuguese or from European origin and mestizos who came from the urban areas of the coast) from the 'non-civilized' population (Black Africans, mainly from the rural areas). The teaching in the colonies was being built, from the early days, within the framework of this duplicity of public, implying a set of modalities of teaching, content and strategies of differentiated school incorporation. However, the type of primary education offered was based on a type of school inspired on the European metropolitan model, with a uniform basic curriculum, academic and, in the case of the schools aimed at teaching the Africans (rudimentary primary schooling) simplified.

Similar to other areas of the imperial dominance, Portugal was late, relative to France and England, in the definition of a colonial educational policy, at least until the mid-1930s in the twentieth century. This lack of definition was considered responsible for the inefficiency of the colonial administration along with the coexistence of opposite opinions about the project of colonization and, consequently, of education. As a result, education governance tended to evidence a centralized tendency, mainly 'direct' in outlook: anticlerical internally, but multi-confessional in the external propaganda; hesitating, at the level of strategies of incorporation of the African masses, and ambiguous in relation to the status that these could adopt in the cadre of the Portuguese colonial administration. In administrative terms, and in practice, the decentralization attempts which gave more manoeuvre to the intervention of the governors and high commissioners in the colonies until the mid-1920s were not able to compensate, from a legal point of view, the tendency of the colonial assimilation to the metropolis. What did change, instead, were the arguments used to justify their new powers. Bear in mind, for example, the discourse about the characteristics of the Portuguese colonialism of exception, that of the 'undefined people between Europe and Africa' (Madeira, 2003: 44–47) turned towards the 'singular predisposition of a hybrid colonization of the tropics', according to Gilberto Freyre, a thesis already divulged in the international circles, through the work of Sir Harry Johnston *The Negro in the New World* (1910), a book referred to by a whole generation of Portuguese-Africans to confirm the thesis of the 'kindness of the Portuguese' in the African colonization.⁵

Different from the paternalistic image that Portugal tried to show in the international circles, and in spite of successive governments (monarchic and republican) claiming for themselves the mission of civilizing as a right of tutelage over people they

considered to be under their political jurisdiction and moral protection, the mission of ‘educating the bodies’ and ‘save the souls’ ended up to be given to the Portuguese Catholic Church. In this respect, the unity of action of the Catholic Church, disputed and controlled regularly at least up to the 1930s, succeeded in moving across the different positions which, in the metropolis and in the colonies, became aligned by divergent conceptions, even contradictory, up to the beginning of the Second World War. In simple words, for the Portuguese Catholic Church ‘to civilize’ meant ‘to Christianize’, a mission for which the regular priests claimed for themselves historical rights. The anticlerical conceptions which attempted to annihilate or control their action in education were of different kinds. The perspectives which were claimed to be of French influence, represented by the liberalism of the eighteenth century, defended a civilizing action Illuminist in its origin based on the respect for equality among men – an argument strongly supported by an essentially legal conception of equality among people.

On the other hand, the utilitarian perspectives, relating the education effort to the exploitation of the colonial resources, considered the ‘education through the inculcation of working habits’ the most viable option, arguments which tended to call forth the efficacy of the association between the ‘civilizing duty’ and the ‘right to explore’. Lastly, a third path – one which ended up by imposing itself in the arguments and practices of the colonial government until the independencies – defended a Portuguese type of ‘assimilation’, crafted in the image of ‘Greater France’, and extending the grandiosity of the Portuguese spirit to the overseas provinces. This thesis suggested that the economic and social advancement of the indigenous population depended on a set of principles moral and spiritual in character. Paradoxically, it was during this phase, coincident with the rise of ‘Estado Novo’ regime that the role of the Catholic Church began to be officially recognized as determinant for the colonization process, that is to say, instrumental to the ‘nationalization’ of the Portuguese Africa.

By implicitly associating Church evangelization with the State action in the ‘assimilation’ of the African peoples, this policy approached the British incorporating strategy which clearly associated for a long time ‘civilizing colonialism’ with ‘State colonialism’. The presuppositions of this association were, nevertheless, very different from the British imperialism ones. The ‘right to explore’ arguments, in juridical terms based on historical accounts, and the ‘civilizing duty’ supported by a moral imperative, articulated to produce a ‘lusophone bread’. This variant was liberal (since it was funded on the idea of economic resource exploitation) and, at the same time humanist, based on the idea of the assimilation of the dark races plunged in the ‘secular night’ to the spirit of the national culture.

The French Civilizing Mission: To ‘Cultivate’ the African Mind

As with the British case, the French presence in West Africa went through different phases. In Gifford and Weiskel’s work, a pivotal comparative study of the colonial systems in Africa, two particularly important periods in the history of French colonization are considered (Gifford & Louis, 1978: 663–711). A first ‘pre-colonial’ period (1815–1890) and a second moment, characterized by the consolidation of the ‘colonial rule’ (1894–1945). During the first phase the French colonizers were faced with two

major problems. In Senegal, due to deficiencies in the colonizing process, the French were having problems both in controlling the rise of the trade communities that were establishing themselves in the coastal areas at a rising rate and of expanding their influence to the interior territories. As such the administration policy began by authorizing teaching in the local languages at the public schools (1816), by tolerating the missionary activity (1820–1830) and it ended up by handing out education to the Catholic Church.⁶ This laissez-faire attitude was justified by the argument that schooling was a means whereby the French influence could be extended and preserved among the traditional authorities, in particular in the mainland territories, ruled by Islamic leaders. In most Haute-Volta schools, in the Ivory Coast and in the northern Islamic territories of Senegal, the French school system task was to educate the individuals who could eventually assume the role of traditional authorities. In these schools, some of them destined for the sons of tribal chiefs and gentile authorities, the curriculum was centred on teaching the French language and some subsidiary subjects related to local aspects of everyday life (Gifford & Weiskel, 1978; Gann & Duignam, 1971). The remaining schools were targeted at the training of interpreters and administrative functionaries aiming at consolidating the commercial relationships and at minimizing antagonisms between the local populations and the French colonial administration.

As a philosophy, the discourse on ‘assimilation’ progressively transformed into a cultural imperialist doctrine, reflecting the wish of forging the political and cultural uniformity of a ‘Greater France’. Education represented a means by which the overseas territories could be integrated in an increasingly expanding empire and a strategy for the transformation of Africans into *black Frenchmen*. French assimilationist objectives manifested themselves in the type of administrative organization, highly centralized, by which the colonies were considered as extensions of the metropolitan territory. However, it would be misleading to think that the assimilation policy was to be the norm in every colonial situation or even that the assimilation policies translated into effective control of the educational matters in all colonies. In spite of the creation of the Colonial Ministry, in 1894, the French were far from ensuring a tight control over the colonial education systems, of providing enough well-prepared teachers, of financing the schooling functioning, a set of factors that cumulated with an ill-defined educational political strategy (Gifford & Weiskel, 1978; Kiwanuka, 1993). In fact, up to the first decades of the twentieth century, the educational provisions were made by the local administration, attempting to respond to the educational needs of each territory whether in quantitative or qualitative terms (Clignet, 1968). At the end of the nineteenth century at the peak of the metropolitan assimilationist rhetoric, the development of the educational structures in North and West French Africa was very much dependent on the funding arising out of private initiative such as the *Alliance Française* or in the hands of Catholic missionary societies.

On the other hand, the French educational policy was very much influenced by the British educational experience, in such a way that the principles of ‘indirect rule’ inspired several colonial governor strategies as with the case of Lyautey, Gallieni or Van Vollenhoven. Appointed High Commissioner to the Maroc in 1907, Louis-Hubert Lyautey administrated the protectorate (1912–1916) by granting his support to the local Islamic chieftaincies and by seeking cooperation with the sultanate regime. His

administration was marked by respect for local habits, both in religious and cultural terms. Joseph Simon Gallieni, on his turn, governed Madagascar (1896–1905) on the basis of the ‘oil spill’ principle considering that education was essential to the development of the local populations. Gallieni interested himself in the local cultures, favouring the local languages protection themes about which he produced extended works and remarks (Dimier, 1998; Clignet & Foster, 1964). Lastly, Joost Van Vollenhoven, appointed Governor General of French West Africa in 1916, endowed the traditional authorities with unprecedented powers and responsibilities in the colonial administration, paying particular attention to the ‘*évolués*’ natives. No doubt Van Vollenhoven was trying to develop the state strengths by using the traditional authorities as counterparts and not as opponents, and certainly this could be considered a device of colonial control devise. Nevertheless, this was much closer to the British ‘indirect rule’ style than it was to the French ‘assimilationist’ or even ‘associationist’ native policies.

The acts approved in parliament, in 1902, calling for the secularization of all schools run by the Catholic Church in West Africa and the climate caused by the Dreyfus affair gave way to a new phase in the organization of the school system in the colonies. The expansion of a European school system and the need to control the missionary supply on education produced a reorganization of the public sector. The two decrees passed by Governor General Ernest Roume in 1903 fitted neatly in the anticlerical feelings that were becoming evident since 1880, when Jules Ferry (Ministry of the Public Education) had promoted a compulsory, laic and free educational school system. Under Roume’s new administration the universalization of education turned out to be one of the central objectives of the French civilizing mission in Africa. Clearly influenced by the thinking of Gallieni and Lyautey, and pedagogically supported by Gustave le Bon and Léopold Saussure theories, Roume considered that assimilation was not a policy attuned to a vast and diverse province such as French West Africa (Le Bon, 1894; Saussure, 1899). By contesting the frenchifying metropolitan policies, Roume thought that the Africans should evolve according to their own lines, and under this conception, the curriculum should be ‘adapted to the colonial needs’. Henceforth a free, secular system of education was created granting particular emphasis to the French language as a medium of teaching. The educational structures were set up in order to respond to the colonial pragmatic needs and were divided in *écoles de villages*, designated to the training of interpreters, the *écoles régionales*, aimed at the training of administration functionaries, and the *écoles urbaines* for the training of Africans who were to fill posts in the French colonial administration. The urban schools directed to the European and to the ‘assimilated’ individuals were designed to work along metropolitan lines whether in terms of the teaching staff or with regard to the curriculum. Rural or regional schools were destined to the native population and, as such, the curriculum was adapted to the local populations’ special needs. These two apparently opposed principles (assimilation/adaptation) were used in twofold ways: one directed at the expansion of school opportunities (at the elementary level), crafted for the majority of Africans; and the other directed at limiting their access of assimilated natives (to the secondary-level school opportunities).

In 1907 Ernest Roume retired and was replaced by William Merlaud-Ponty in the government of French West Africa. Merlaud-Ponty’s perception of native educational

policy could not be more dissimilar than that of his predecessor as was shown by his circular published in 1909 under the theme of *Politique des Races*. In this document the new Governor General clearly demonstrated his preference for the principle of 'direct rule', thus implying a reduction of the intermediaries between the local administration and the traditional authorities in the villages. In this way a new native policy orientation emerged, downplaying the role that had been previously accorded to the traditional authorities in the French colonial administration. In educational terms Merlaud-Ponty was very well aware of the French civilizing mission towards the Africans, and as a result the 'adapted education' path was the object of serious revisions. In 1914 on the eve of the First World War, Merlaud-Ponty appointed Georges Hardy as the new General Inspector for Education in French West Africa. Though they were never promulgated, Hardy's directives reinforced the laws and decrees passed by Ernest Roume from 1903, marking the return to an ambiguous educational policy midway between the consolidation of a metropolitan school model and the construction of a school system 'adapted to the needs of Africans' (Gifford & Weiskel, 1978; Gann & Duignam, 1971). However, Hardy's efforts apparently concentrated on the separation of those fit to receive a European type of education drawn from the image of the metropolitan school system and, at the other end, a mass schooling model destined to incorporate the vast majority of the African natives.

In any case, the superposition of different strategies and discourses about the colonial education policy allows us to question the idea, much celebrated by traditional historiography, of a homogeneous and universal type of school curriculum aimed at the transformation of Africans into 'black Frenchmen'. On the contrary, we may perceive that perhaps until the 1930s the policies pursued in the French West Africa territories tried, precisely, to avoid the excessive frenchification of the native population. For that purpose the continuous prevalence of a dual educational system – one for Europeans and assimilated natives and the other aimed at the mass of native population, regardless of the more or less importance given to the traditional authorities – was always a strategic means of controlling the eligibility for cooperation with the colonial administration.⁷ That does not imply, however, the workings of a straightforward imperial ideology of assimilation. As I have tried to show, the building of a school curriculum in French West Africa was very much conditioned by individual strategies and governing styles predicated on the Governor General's interpretations emanated from Paris. Likewise, the discourse on 'adapted education', although inspired by the British colonial south-Saharan Africa experiences, worked more often as a constraint than as a possibility for the majority of natives. It meant, generally speaking, an emphasis on a practical and moral education while downplaying a more scientific curriculum.

Concluding Remarks

Lord Lugard, Governor General of Nigeria (1914–1919) and the great colonial doctrinaire between the two wars, was a forerunner in the comparison of the British and French colonial systems. Lugard knew well the French colonizing doctrines and he maintained close contact with Maurice Delafosse at the head of *École coloniale* (1909–1926) as well

as with his successor, Henri Labouret, with whom he created and directed the *Institut international des langues et civilisations africaines* (London). Lord Lugard cherished the opinion that, by the end of the nineteenth century, the French colonial doctrines had evolved from assimilation to association and that they were approaching the ‘indirect rule’ British policy. On the other hand, Maurice Delafosse had, more than once, contested the idea that ‘indirect rule’ was a prerogative exclusive to the British colonial system:

Il serait plus sage d’observer ce que font les Anglais dans celles de leurs possessions qui sont analogues aux colonies françaises voisines, Gambie, Sierra Leone, Nigeria, Gold Coast où la proportion de l’élément européen et de l’élément indigène, de même que le stade d’évolution de ce dernier, se présente approximativement sous le même aspect qu’au Sénégal, en Guinée, en Côte-d’Ivoire et au Soudan. Nous constaterions alors que cette centralisation que d’aucun reproche si fort à la France dans son administration coloniale est aussi accentuée chez nos voisins que chez nous.⁸

The lack of continuity between the idealized discourses and the local practices was, more frequently than one thinks, a fact transversal to any of the colonial empires which have been studied. I should add that, in my opinion, such discrepancies were mainly associated with local or interstate contingencies and constraints (related to historical conditions, geographical locations and concrete political rivalries) rather than to divergences or even ideological antagonisms related to programmes of action (or *scripts* of government) of a national–metropolitan nature. In fact, when we focus on discourses which circulate in the interior of the different colonial contexts, the contingencies of the colonial administration and the ambivalence of the European policies concerning education reveal themselves even more clearly. This suggests that the colonial exercise was ruled by, not rarely, a set of commitments, arrangements and *bricolages*, *scaffoldings*, tending to articulate orientations very often abstract and general, making use of schemes, techniques and informal arrangements of discourse regulation, specifically in the field of education and in the teaching of the natives.⁹

Needless to say, at least until the eve of the First World War, the definition of an education policy in the African colonies was more dependent on the native policies of the colonial powers and on the prevalent views about the natives’ role (and the Europeans) in the colonization process than anything else. As such the educational debates were subordinated to the doctrines that originated in different fields of production (native policy, colonization doctrines, economic exploitation, work force formation, etc.) than the strictly pedagogical or educational fields (theories and philosophies of education, models of schooling, types of curriculum).

Notwithstanding, when we compare the Portuguese and French colonial doctrines we come across the same type of hybridizations which also show at the level of the educational discourses. The construction of a dual educational system, one for the masses and the other for the Europeans and assimilated (or *evolúés*), was a feature characteristic both of the Portuguese and French colonial educational structures. The appropriation of the concept of ‘adapted education’ by the Portuguese and French colonial administration also bears some resemblances since it implied a particular strategy, somehow ambiguous, on the educational system supply-side. For the Portuguese colonial

administration, the concept of 'adapted education' was tied to a restrictive type of curriculum aimed at the masses, with emphasis on agriculture, manual skills and domestic sciences, implying a strong moral character. In this respect, French and Portuguese doctrines converged into an understanding of the type of moral teaching that should be given at the primary school: it involved a secular moral education, based on the principles of the Enlightenment, as opposed to the British understanding of a truly religious social gospel committed to the formation of character which was strongly embedded in the evangelic Protestantism. These two conflicting ways of envisaging the human development through education also had consequences at the colonial level. For the Portuguese and French administration *education* was a right that should be guaranteed to each citizen, a right that committed the State to the provision of an educational free, compulsory and secular school system. To the British colonial administration *education* was a privilege to be privately acquired, making possible to any group, association or institution to come forward with a particular type of educational offer. In the English tradition education was not a given fact; it was a market for individual and collective advancement closely tied with economic and social development.

Therefore, the assimilation in the Portuguese and French civilizing educational doctrine implied an increase in cultural homogeneity and huge standardization, a fact that called forth centralized mechanisms of diffusion and appropriation of school models and pedagogical theories (with clear implications on system organization, curricula, teacher training, funding and administration). Somehow paradoxically, language issues were pivotal in changing the politics of education since the Portuguese and French colonies were taught in the imperial language downplaying the vernaculars as a medium of teaching. The British, on the contrary, were more concerned with the formation of habits, of skills and of a conduct attuned to the formation of a workforce prepared to accept the concepts of individual and collective progress and modernization. As long as the masses could master this understanding, the language of apprenticeship was secondary for that matter. Due to the difficulties of 'governing at a distance' the costs involved in assimilating the Africans to the European metropolitan mores were much higher than in the British colonies where the civilizing task was supervised but had been handed out to the private initiative.

To analyse the field of utilization of these ideas, concepts and theories is not the same as to analyse the set of strategies which are implied in the defence of a particular kind of *Education* for the African people. It is not a question of perceiving which meanings are linked by each colonial nation to the notion of 'direct government' or 'indirect', 'colonization' or 'nationalization' (and, the same way: 'civilization', 'instruction', 'education', 'assimilation', 'association', 'adapted education', 'teaching of adaptation'). The procedures which support the doctrinaire building that constitutes the school system, in articulation with the attempts to maintain or modify the appropriation of the discourses with the knowledge and the power they carry with themselves, are difficult to separate one from the other (Foucault, 1977 [1971]). It becomes, therefore, indispensable to identify and organize the reading of facts which compound these discourses: to locate the debates and to analyse the controversies, to identify the themes and arguments; to describe the structure of the intrigue; and finally, to perceive the constitution of the 'societies of discourses' through ideas, theories and concepts which are used in the colonial government, in a general sense, and their

effects upon the government of the colonized subjects, in particular (Foucault, 1966 and 1969). Nikolas Rose once wrote that the concepts ‘are more important for what they do than for what they mean’ (Rose, 1999: 9). I would like to add, quoting António Nóvoa (1998), that we cannot understand the colonial discourse without being able, ‘to think about the *other* in time of our own thinking’, asking questions about how discursive events about this *other* are produced, and how these statements are related to each other in order to constitute a ‘discursive practice’ (Foucault, 2005 [1969]: 38–39, 68 and 159).

Notes

1. About that we can show some paradigmatic examples, either in France or in Portugal: Jules Ferry, a most bitter assimilator in the metropolis, reviews his position after an inquest which took place in Senegal; Antonio Enes was very critical in relation to the role of the Church in the education, at the end, whilst General Governor of Moçambique goes in defence of an important role for the missionaries in the colonial context; Lopo Vaz de Sampaio e Melo, who defended the persecution of religious orders in the metropolis considered, at the end, their destruction in the colonies appalling, etc.
2. While strategies of power, the principles of government imply in complex and variable relations between the calculations and actions of those who look for exercising the domination over a territory, a population, a nation and a microphysics of power acting at a capillary level among the varied practices of control which develop at the level of a given territory. “To govern at a distance” involves processes of translating different kinds through which associations between the objectives of the authorities which wish to govern and the individual projects of organization, groups and individuals which are subjects to the government are forged. EDUCATION AND STATE FORMATION IN ITALY

Donatella Palomba

Introduction

In many respects, the evolution of the Italian education system since the Unity of Italy (1861) can be investigated according to an interpretation that is not too far from the one usually adopted in international literature about education and state formation. At a deeper level, however, failing to take adequately into account the distinctive features of Italy's socio-political situation might prevent an understanding of the process itself.

This chapter is intended to make the following point: from its origin in 1861 to very recent years, the Italian State has constantly suffered from a lack of legitimation and full sovereignty, which has strongly affected all its political events and has had a particular influence on the raising of national awareness and the possible role of education therein. Although the reasons for this phenomenon have not always been the same during the time span considered, the full acknowledgement of the legitimacy and sovereignty of the Italian State has been limited for a much longer time (and more severely) than is emphasised, especially in the literature on Italy's education system.

This has brought about a somehow paradoxical situation, marked by a long-standing national feeling on the one hand (suffice it to remember Dante's *invettive* in the *Comedy* or Petrarch's *Canzone all'Italia* in the fourteenth century), and a relatively belated and troubled process of state formation on the other hand, with sovereignty being continuously challenged and apparently never fully achieved. In turn, this has negatively affected the development of a sense of belonging to the new nation state – the weakness of this sense of belonging having often been denounced from the Unity of Italy up until today.

In order to understand the roots of this situation, issues of international policy and international balances need to be considered in the first instance. Upon the unification of Italy, these balances were seriously challenged by the deterioration in the relations with the Pope and the Vatican State. Later on, they played a key role for different reasons, both early in the twentieth century and after the Second World War, to an extent that has probably not been investigated enough yet, especially in terms of education.

During the period from the Unity of Italy to the Second World War, the legitimacy of the Italian State was first challenged by the Pope not recognising the State itself, with all the implications this had both domestically and internationally in the relations with

European Catholic powers. Later on, the Concordat signed by Mussolini's Government and the Holy See (1929) somehow settled this *vulnus*. Very soon, however, the authoritarian nature of the Fascist regime questioned in turn the full recognition of the Italian State's democratic legitimacy vis-à-vis many other countries.

In the years after the end of the Second World War, the newborn Italian Republic had to prove its *bona fide* democratic nature and break with its authoritarian past, on the one hand; on the other hand, its sovereignty – meant as the real possibility of Italy's choosing its own government – was conditional on the geopolitical situation resulting from the Yalta Agreement reached by the victorious powers to set out post-war world balances.

This conditioning had a profound effect on the ways in which democracy evolved in Italy, which needed to re-establish its institutions and, in particular, try and define the features of an education system that was supposed to shape the 'new' democratic citizen, according to guidelines that were particularly complicated by a tangle of domestic and international factors in which both Catholic and communist forces played a crucial role.

Therefore, the deep change in international balances from 1989 onwards had a very strong impact on both the politics and institutions of the Italian State, by restoring greater autonomy while upsetting a reference framework that had lasted for almost five decades. That was the so-called transition to the Second Republic. This transition period is actually still in place and, once again, has profoundly affected the education system too.

This chapter intends therefore to follow two directions: on the one hand, analysing the evolution, structure, and features of Italy's education system according to an interpretation that is similar to that applicable to most other European nation states; on the other hand, constantly refocusing on the distinctiveness of the Italian situation as the key interpretation of this analysis.

The Problematic Framework

The Unity of Italy was achieved – as in other countries – through a process of reunification of areas that had been previously governed by rulers of different dynasties or had been under the direct rule of a foreign government (as was the case with Lombardy and Veneto under the Austrian Empire). In addition, a significant part of the country was under the Vatican State, headed by the Pope.

As a consequence, the Italian State was founded in opposition to the Papal State, by first (1860) annexing most territories that had once belonged to the Pope, except Latium and Rome. About ten years later (in 1870), with the well-known 'Breach of Porta Pia', Italian troops marched into Rome and proclaimed it the capital of the new State, while the Pope retreated into the Vatican enclave. As the years went by, the conflict became less fierce, although it was not until 1929 that the Lateran Pacts signed by the Fascist Government led to mutual recognition, with the birth of the Vatican City State. Nevertheless, this recognition did not completely settle the dispute.

There is a very extensive bibliography of historical and juridical texts on Church–State relations and the 'laicity' of the State (Veneruso, 1972, 2003; Lariccia, 1971) which cannot be dwelt upon here. There is no doubt, however, that education – namely

the school system – was one of the major battlefields in the Church–State conflict, for quite understandable reasons. The notion of the national education system as the primary institution of citizens' education – consequently involving public responsibility – clashed with the Church's view of education as natural right of families which, however, must be enlightened and guided by straight faith: this implies that education institutions to which families must/can entrust their children cannot but be inspired by, and accountable to, the guardian of faith itself, i.e. the Catholic Church.

This conflict was not something peculiar to Italy. The specificity of the situation in Italy was that the very legitimacy of the Italian State – and, consequently, of its educational action – had not been acknowledged by the Church for a long time, because the State had been established by an act of 'aggression' against the Papal State and the Pope himself was both a Head of State and universal religious authority; hence the contrast over education was of major significance.

This aspect, while not being the only criterion to be taken into account for the interpretation of the history of united Italy and of its education system, should however be considered as the background and framework within which events took place, in order to realise the distinctiveness of the situation in Italy, as compared to other countries, at the time of the state formation.

The Birth of the Italian Kingdom and the Casati Law

In the first semester of 1859 a highly surprising event took place in the frame of the European political evolution: Cavour, Prime Minister of a small Italian State, the Kingdom of Sardinia, skilfully took advantage of Paris's mistakes in the evaluation of the Italian situation and of the even greater diplomatic mistakes by Vienna. He thus succeeded in channelling the centuries-old conflict between the two mightiest European states, France and Austria, into a war which would lay the foundations of an Italian Nation State (Ugolini, 2001).

When the two great empires, the Napoleonic and the Asburgic, realised that the only state to take advantage of the war was the Kingdom of Sardinia, they tried – without effect – to stop the fight (Villafranca's armistice), to engage an impossible reverse motion.

In fact Great Britain, trying to prevent at all costs the war from overflowing the Italian theatre and trespassing on European and worldwide territory, adopted Cavour's policy, that is the thesis according to which the establishment of the Italian Kingdom was the price to pay to recover the international equilibrium and thus make up for Paris's and Vienna's incautious and deleterious policy.

So in just two years, in this international context, the unification of Italy was accomplished, bringing about the quick establishment of a 21-million inhabitant new national state.

By February 1861, in Turin, the Italian Parliament started its sessions, in a somewhat gloomy atmosphere for the new State that had to face several serious problems big enough to justify the lack of international confidence in its life expectancy.

The first problem was related to the completion of national unity: still outside the kingdom's boundaries were Veneto and Latium, and above all Rome, considered by acclamation as the new State's capital. But Rome was already the capital of a state, the

Papal State, whose sovereign, Pius IX, also held religious powers of divine origin and with universal jurisdiction.

Thus the second problem was to persuade the Pope-King to split his two powers, temporal and religious, and give up the first one. That problem had already been debated for many years by the international secular and catholic circles. Pius IX's ultimate answer came – unequivocally – when, in the spring of 1860, some former papal territories expressed their will to recognize Vittorio Emanuele II as their own king. The Pope excommunicated the Piedmontese king and all those who made an attempt on his territories; he did not recognize the new State and consequently ordered the Catholics not to take part to the institutional life of the Italian kingdom. This created a deep inner cleavage in the new Nation and, on the international side, made it hard for Catholic States to recognize the Italian State.

This international isolation made it even harder to solve another problem, maybe the gravest for the new ruling class: the financial crisis due to the sum of the seven pre-unitary states' budget deficits. It was evident that Italy had to increase its income internally and cut expenditure: failing to do that would mean losing the newly gained independence.

And then the issue which was perhaps the most important: one State was made out of seven, but there was the need to create those unifying norms (such as laws, weights, and measures) and those infrastructures (such as streets, railways, and postal services) necessary to make the unification real and to make people perceive it as an effective reality. To echo a famous motto, 'once Italy had been created, Italians had to be made', through many complex actions in which education (discussed below) had a role. For a few months, at the beginning of 1861, it was thought to have its politics managed by an administratively decentralized State, but the risks connected to such a hypothesis (catholic opposition, international isolation) forced the ruling class to take a decision to centralise – in an effort to reduce internal strife.

For the preservation of the unity a basic consensus was achieved by all the political forces of the Italian peninsula, the liberal and conservative right wing as well as the democratic and revolutionary left wing. In the first 15 years of its institutional life, owing to such consensus, the Italian State could complete its unification. (In 1866 Veneto was annexed, followed by Rome and Latium in 1870.) It could also achieve the legal, administrative, financial, and transport unification of the country and be recognized by the other states. Notwithstanding such positive outcomes, the problems related to the Catholic opposition and to the structural financial weakness intensified.

After 1870, the Pope was far from acknowledging the loss of his temporal power: he declared himself 'prisoner' in the Vatican, and systematically incited the Catholics not to support the new State's institutions (*Non expedit*),¹ in expectation of a providential restoration of the *status quo ante*. The new State, with its structural weaknesses, just about had the economic strength to support the unity already achieved, but it was not capable of investing enough to create the hoped-for transformation from a rural to an industrial economy.

Any reform in nineteenth-century Italy had to satisfy two main conditions: it had to cost the bare minimum needed, and it had to be able to survive the inevitable Catholic opposition.

Education laws were the first to have to fulfil such conditions. So did the Casati law, enacted by the Piedmontese Government with plenipotentiary powers in November 1859 – at the very beginning of the unification process. The law, comprising 380 articles, fully regulated all parts of the educational system. When it was approved, it was neither enthusiastically welcomed nor explicitly rejected: it was considered as a temporary law for a temporary political situation. Its main purpose was to show the willingness of the Kingdom of Sardinia to meet the requirements of Lombardy, which was then the only new region annexed. Gabrio Casati was the first Milanese in the government and his law was intended, at the moment in which it was passed, only for the Piedmontese and Lombard territories.

Actually, the Casati Law ruled Italian education up to 1923, when, under the Fascist Government, it was replaced by the Gentile Reform. This juridical longevity was due to the fact that after the unification of Italy it was quickly realised that such a law – outlined and brought into force in only four months – responded perfectly to the delicate social and financial equilibriums maturing in the new State after 1861. Gabrio Casati was a conservative Catholic, and he had intended the law to be non-ideological, not too directive of families and communes, and not very expensive for the Treasury. Moreover, his law had the merit of having been accepted by Piedmontese and Lombard Catholics without too many reservations.

Relying on such qualities, the Casati Law was progressively enforced in the whole Italian Kingdom as unification was being achieved. Right from its first enforcement, many scholars and experts of education highlighted its faults and contradictions, but such claims faded whenever it came to suggesting an alternative text, for fear of having to face insurmountable ideological, political, and financial problems.

The law provided for a four-year elementary school, divided into two periods of two years each. Attendance of the first two years was compulsory for all pupils aged between six and eight. After elementary school, different branches of secondary education were established: classical secondary education, divided into a five-year lower cycle (*ginnasio*) and a three-year upper cycle (*liceo*); lower and upper technical education (a three-year technical school followed by a three-year technical institute); and two- or three-year ‘normal’ schools for the training of elementary teachers.

This law – and relevant enforcement regulation, passed in 1860 – set its mark on the very concept of Italy’s education system and established its foundation for many decades. It is therefore proper to dwell upon it in order to highlight the features that are strongly linked to state formation.

The Casati Law was traditionally criticised by Italian education historiography in the second half of the twentieth century for being selective, for providing different branches of education with a clear hierarchy, and for being ‘centralistic’, as it imposed the same system on the whole country, leaving little autonomy to local authorities.

Despite the fact that this criticism, among others, was raised right upon the passing of the law (Semeraro, 1996; Talamo, 1960), one might argue that the emphasis placed on it in the twentieth century suffered from an *a posteriori* interpretation given on the basis of the hottest issues of that period, rather than based on a careful consideration of the context in the mid-nineteenth century.

As regards centralisation, in the situation outlined above, while the country was getting unified with so much resistance and there remained the unsolved problem of the relations with the Pope, it is no wonder that the ruling class, which had bound its destiny to unification, chose to keep a firm central grasp, especially considering that in many regions the Church exerted a strong influence on schools and that a significant part of the teaching staff was made up of clerics, even in public schools.

However, the 'centralist' policy preference met with some hesitation and opposition, not least because the liberal ruling class was in turn quite opposed to a statist view of education (Soldani & Turi, 1993: 18), and, as stated above, had seriously considered a more decentralised approach. Therefore, efforts were made to try and reconcile the different demands. In the covering report of the law itself, the choice was discussed also on a comparative basis. With respect to some European models – the British one, with a very limited state role; the Belgian one, with private and public schools competing; the German one, with the highest degree of state authority over education – Italy chose a 'system of medium liberty, supported by those cautions that keep it into its boundaries and by those guarantees that defend it from manifest and hidden enemies that might spoil it and its fruit' (*Relazione*, 1859, in Talamo, 1960: 73). The reference to the opponents of the new State could not have been clearer.

As to the criticism about the school system structure – with particular regard to the mutual positions of classical and technical education – the (few) views that interpret the Casati Law without forgetting to set it in both a historical and comparative context seem much more convincing.

According to Barbagli:

The most interesting thing – which has instead been neglected by many scholars, all intent to prove the reactionary nature of the Casati Law – is that the education system resulting from that law – if compared to those existing in Europe at that time and those that followed in Italy from 1923 onwards – was relatively open, in that its internal structure was such as to foster relatively high university attendance rates. (Barbagli, 1974: 81)

Barbagli continues the analysis by stressing that there was no internal differentiation in elementary education in terms of schools for pupils willing to pursue their studies and schools for those who did not mean to. Furthermore 'more than at the elementary school level, however, the relative openness of Italy's education system was to be found at the lower or upper secondary education level' (Barbagli, 1974: 82). The opportunities of entering higher education were not exclusively restricted to students coming from academic secondary schools: access to the Faculties of Science and Engineering was possible for pupils coming from the physics and mathematics branch of the *Istituto Tecnico Superiore* (upper secondary technical school) (Barbagli, 1974: 82–83).

In short, one of the distinctive traits of the Casati Law was that no school in the whole education system was conceived as a 'blind alley'. This feature can be understood in relation to the education policy undertaken by the Italian ruling class, which was supposed to ensure the growth of the new State, also from a political standpoint.

If this growth was to be founded on education, it needed to find a practicable way between the need for selection and that for socialization. That meant not restricting participation in the school system too much, in a situation in which schooling was already hindered by socio-economic backwardness, especially in some areas of the country. The main target was therefore the education of the middle classes, through relatively 'open' channels at secondary level, with a view to possibly fostering some social mobility. If the focus on technical education might have been considered inadequate by some of the most advanced productive forces – especially in some regions of northern Italy (Semeraro, 1996) – it was however probably even more than the global economic situation of the country required and allowed for. The model of social control through education adopted by the ruling class clashed with resistance from reactionary groups, while, on the other hand, the social demand for education – especially at the elementary level – was still low, even in the North.

'Our school system resulted, as it were, from the convergence of the education policy undertaken by the Italian ruling class and the difficulties in creating an adequate demand for education among people' (Barbagli, 1974: 99). The relative openness of the education system stemmed from the fact that in a situation of poor attendance, greater selection would have been counterproductive.

The law was quite successful in promoting the education of middle classes: enrolments grew considerably – especially from 1870 onwards – in technical institutes above all. Gradually, during the following 15 years, the concern became that lower classes too be reached in a more direct way, by promoting elementary schooling and, in particular, by enforcing compulsory education, also in order to bridge the gap between school levels.²

In 1874, the new Italian State balanced its budget for the first time. In 1876, when the first left-wing government came to power, one of the first measures adopted was a law (*Legge Coppino*) that aimed to make compulsory schooling as real as possible, providing sanctions for offenders and regulations to facilitate the establishment and maintenance of schools in communes.

The Coppino Law also began to better define the 'formation of citizens' in elementary school syllabi. Rather than a true subject, the Casati Law had envisaged 'readings' on national history – though mainly on the Savoia dynasty's – national geography, and citizens' duties to God, their families, and the country (Santerini, 2001: 19). The Coppino Law, instead, included the *First Notions on the Duties of Men and Citizens* among the subjects taught in elementary school syllabi – this was particularly meaningful, considering that the law equally abolished the compulsory teaching of religion in elementary schools.

Then, the last two decades of the nineteenth century were marked by a much greater emphasis on the formation of citizens in elementary school. This topic was included in the 1888 curricula – inspired by educational and pedagogical positivism – which had been developed by Aristide Gabelli, a renowned educationalist (Santerini, 2001). The need for education as 'national pedagogy' was even further emphasised in the curricula designed in 1894 by Baccelli, which criticised those of 1888 in that they had focused too much on knowledge content and not enough on general education (Ascenzi, 2004: 98 onwards). The strengthening of 'national pedagogy' certainly responded to the need

to ‘provide new and greater legitimation to the political class that had achieved unification’, at a time when socialist and Catholic opposition was growing; elementary education was thought to be the best channel for this legitimation, as emphasised by Minister Baccelli himself (Ascenzi, 2004: 113).

In that context, the call to ‘make Italians’, usually credited to Massimo d’Azeglio, was revived. The famous sentence ‘We have made Italy, now we must make Italians’ was not proclaimed as such by d’Azeglio; instead, it was pronounced in 1896 by Ferdinando Martini, former Minister of Education, who recalled and emphasised a different expression by Massimo d’Azeglio himself³ (Soldani & Turi, 1993: 17). Regardless of the philological dispute, this episode confirms that the issue of the role of education in the formation of citizens had become crucial.

Under Giolitti’s governments (1903–1914), the State budget was more under control, and opposition became less fierce between most liberal forces and a significant portion of Catholic ones; this allowed major changes to be introduced in school structures. In 1904, the Orlando Law raised the compulsory age to 12 years, among a set of measures intended to widen social participation in education.

In 1911, the Daneo-Credaro Law shifted responsibility for elementary education from communes – where Catholic influence had been very strong in many cases – to the State. Due to Catholic opposition, the measure was only enforced in those communes that were not provincial capitals. The law also included further measures for popular education.

Therefore, on the eve of the First World War, the relative easing of tension with Catholics (the *non expedit*, in particular, had become less strict) and the better economic situation led to greater emphasis being placed on the development of the education system at the lower levels. The opportunity of introducing a more comprehensive structure at lower secondary level began to be considered. On the other hand, in the same decades, the rapid growth in secondary-school-attendance rates caused problems in terms of jobs available for school-leavers and also in terms of education quality – as argued by many contemporary politicians and intellectuals. As a consequence, the introduction of measures to restrict the number of secondary school pupils began to be discussed and was supported by non-conservatives as well (Canestri & Ricuperati, 1976; Semeraro, 1996). Idealist philosopher Giovanni Gentile recalled this controversy and these positions when he was called to serve as the Minister of Education after the rise of Fascism and worked out provisions to reform the education system.

The *Riforma Gentile*

The so-called Gentile Reform revised the education system as a whole, reorganising its central and local administration with a significant reduction of the number of bodies involved, and introduced several provisions covering virtually all key aspects of Italy’s education system.⁴

With regard to the school system structure, the reform designed a system whereby, after a five-year elementary school cycle, a differentiated structure was provided.

Compulsory education was raised to 14 years of age, and a dead-end channel was created: the so-called complementary school (*scuola complementare*), lasting three years, for pupils who did not mean to pursue their studies. Classical education kept its structure: a five-year lower cycle (*ginnasio*) and a three-year upper cycle (*liceo*). In addition, a science branch was created: the *liceo scientifico*.⁵ Technical education was supplied by technical institutes, while ‘normal schools’ were changed into elementary teacher-training schools (*istituti magistrali*). A *liceo femminile* (girls’ upper secondary school) was also created: it did not make pupils eligible for higher education and was meant (among other things) to divert a significant number of girls’ enrolments from teacher-training schools, thus depleting the supply of female teachers.

Consistently with Gentile’s philosophical approach, the school system was founded on the pre-eminence of philosophical and classical studies, namely philosophy. Nevertheless, at lower levels, where the ‘light’ of philosophy could not shine, religion recovered its educational role; hence, in elementary schools, ‘the teaching of Christian doctrine according to the catholic tradition was considered as the foundation and crowning of all degrees of elementary education’ (Royal Decree 1923, Article 3).

Therefore, the Gentile Reform changed the school system – and the socialisation and selection approach adopted until then – not least in connection with the concerns voiced by many politicians and intellectuals in previous years. Secondary school enrolment was to be reduced, in order to safeguard the quality of education and to better match the labour market demand. On the other hand, however, driving too many pupils out of the school system prematurely would have caused a problem of lack of socialisation – a big risk, indeed, at a time when the new regime was just starting to establish itself. The matter, therefore, was not so much reducing the global number of pupils as reducing it in ‘open’ channels. That was the aim of creating a dead-end school after the elementary cycle – a solution that the Casati Law had never envisaged. Three-year complementary schools were supposed to be the backbone of education for the people: designed for the ‘humble citizen’ (*il modesto cittadino*) (Canestri & Recuperati, 1976: 141) and ideally meant to provide ‘education for all’, if compulsory schooling until the age of 14 had been complied with.

If this aspect can be interpreted in the light of the openness/closeness issue described above, the reform action as a whole is a complex interpretation problem (Canestri, 1983) which cannot be addressed here as it should. The complexity of interpretation stems from a tangle of elements. On the one hand, the historical context referred to – i.e. the early years of Fascism (before the notorious murder of Matteotti, in 1925, marked its transformation into a ‘regime’) – was a transition period with elements of continuity as well as of rupture, with the previous situation having an influence on the government’s action. On the other hand, Gentile was a philosopher and intellectual with a complex personality (Coli, 2004) holding an ideal and conceptual view of Fascism and of the role of education, which was not necessarily in tune with practical policymaking needs.

Therefore, the *Riforma Gentile*, defined by Mussolini as ‘the most fascist of reforms’, was actually an object of appreciation and criticism that cannot be identified and linked with any clear-cut political groups.

It was certainly an elitist selective reform and, as such, was criticised by socially committed groups. In Gentile’s philosophical and intellectual view, however, the elite

had to be strictly selected according to its merits: this was something that disappointed bourgeois middle classes, whose approval was instead sought after by Fascism. On the other hand, the idea of an essentially humanistic elite culture was a cause of concern to emerging industrialists, while Catholics – who were satisfied with some aspects of the reform, like the compulsory teaching of Catholic religion in elementary schools – could not agree to the idealistic secular framework of Gentile's Reform as a whole. One should be reminded that the reform had been designed in cooperation with first-class intellectuals, representatives of a culture that was far from reactionary (including Giuseppe Lombardo Radice, who had drawn up the 1923 elementary school curricula⁶).

The discontent coming also from sectors of public opinion that the Government wished instead to please led to the so-called policy of readjustments carried on by the successors of Gentile (who left his post as a minister in the middle of 1924). Gentile himself referred to this policy as a form of 'betrayal', especially with regard to some provisions aimed at lessening the selectivity and strictness of education.

Measures were adopted to reform 'dead-end' schools, which had been completely unsuccessful in attracting enrolments. As a result, between 1929 and 1931, the lower secondary education cycle was reorganised by creating the so-called *scuole di avviamento al lavoro* (schools preparing for work) to replace complementary schools, thus reintroducing at least the opportunity for pupils to be made eligible for technical institutes and teacher-training schools.

The Fascist 'Regeneration'

In Gentile's vision, linked to the Ethical State and to an education conceived as a philosophy of spirit, the connection between the educational system and the State, is undoubtedly very strong, as having an authoritarian impact on all aspects of school life. In this light, Mussolini's definition as 'the most Fascist of reforms' is perhaps well grounded. On the other hand, however, the development of the system as it had been conceived by Gentile clashed with the political need to maintain the consensus of the different social strata (Canestri & Ricuperati, 1976: 142), and was, in some respects, inadequate to bring about an in-depth educational 'Fascistisation', which was subsequently achieved through different routes, not limited to school.

Numerous measures were adopted to this end by the various ministers who followed Gentile. Suffice it to mention the establishment of *Opera Nazionale Balilla*, a youth organization aimed at controlling physical education in schools, which, in 1929, came directly under the authority of the National Education Ministry (*Ministero dell'Educazione Nazionale*); the adoption, again in 1929, of the State Common Text (*Testo Unico di Stato*) for elementary schools, followed, in the 1930s, by deep changes in curricula and in many aspects of school life, for the purpose of a 'Fascist regeneration of schools' (Pazzaglia & Sani, 2001).

In 1929 the signing of the Lateran Pacts brought about the recognition of the Italian State by the Holy See with a 70 years' delay, and the establishment of the Vatican City State. The Pacts mark a crucial phase in Italian history, their importance going beyond the Fascist era. Despite strong opposition, they would in fact be subsequently included

in the Constitution of the new Italian Republic which came into force in 1948, and be replaced by a new treaty as recently as 1984.

The delicate *quid pro quo* at the basis of the Pacts has been made the object of several studies and has been differently interpreted, especially with reference to the new balance of powers established between the State and the Church (Spadolini, 1967; Margiotta Broglio, 1969). Undoubtedly, the State did make several concessions: with reference to education, Catholic religion was recognised to be the ‘foundation and crowning’ no longer of elementary school alone, but of the entire school system. On the other hand, at the same time the State was forcibly indoctrinating pupils (to the point of speaking of ‘Fascist Mystics’ in education). Hence, education of the young came to be once again the setting for a confrontation for control over citizen formation, including outside the school, as, for instance, in the field of youth association movements (Jemolo, 1955).

Considerable concessions had therefore been made to obtain the recognition of the State by the Holy See, which also meant getting rid of that delegitimization which had had such a strong impact on Italian political life. Paradoxically, a guarantee of the fact that these concessions would not imply that the State would entirely surrender its prerogatives came precisely from its authoritarian character – although this very nature would impact on the democratic legitimisation of the State itself.

A deeper analysis than the one that can be done here would look at the *Carta della Scuola*, presented by Giuseppe Bottai, who had become Minister of Education in 1936. As it was intended to be ‘the document of the full Fascist maturity in the political/programmatic approach to the relationship between economy, work, society and education’ (Bertoni Jovine, 1958: 364), a careful examination would allow to better understand the general concept of the relation of education and society in the last period of the Fascist regime. However, it remained mostly unimplemented, owing to wartime and then to the fall of Fascism itself, except for a measure which was relevant in itself and for its future developments, i.e. the law, passed in 1940, that unified the lower courses of the secondary schools (*ginnasio*, technical schools and teacher-training schools), leaving out vocational and artisan courses (the latter not leading to any further study).

After the Second World War

Following the end of the Second World War, the reconstruction of the defeated Italian nation had to go well beyond merely making good the material devastation: it had to face once again, in a sense, the issue of state formation.

As a result of the referendum of 2 June 1946 Italy abolished monarchy in favour of the Republic. The years which immediately followed the Second World War were marked by a unitary approach to reconstruction, with a government that saw the participation of all the anti-Fascist forces which, together, after long and complex discussions, drafted the new Republic’s Constitution, which came into force on 1 January 1948. The Constitution fully took into account the need to counterbalance forces that could cause the country to revert to the past, both recent and distant. On that need for ‘countering’,

the necessary agreement had been reached among forces which were deeply different and even opposed owing to their ideological background, political structure, and social representativeness, i.e. Catholic forces, liberal ones, and those influenced by Marxism.

Soon enough, though, a number of factors, the most important being the worsening of the international scenario, led to the break-up of this unity. This was replaced by a situation whereby more than the endorsement of the national spirit, what prevailed were those which have been defined as 'separate belongings' (Scoppola, 1993: 32), i.e. allegiances to the political and ideological forces mentioned above, which in turn referred to different supranational forces, in a world which was about to split.

A decisive event was the first general elections, which were held in 1948. The victory of left-wing forces would have strongly unbalanced international equilibria as they had come out of the agreements negotiated by the victorious powers. However, even after the moderate block dominated by the Christian Democrats prevailed, the revolutionary perspective was still the main scenario for the left-wing forces influenced by Marxism, preventing them from fully endorsing 'normal' reformist policies.

On the other hand, the Catholics were for the first time fully taking part in Italian political life and, while recognising the State, they could not but be influenced by their past history, both in their relations within Italy and with the Vatican State. The difficulties encountered in building up a national identity were compounded by the 'very high price paid for the *Questione Romana*' and the *non expedit* (Scoppola, 1993: 27; Rusconi, 1993).

The majority of Italian citizens' ideal allegiance to one or the other of the forces that presented themselves as two largely universal 'churches' made it even more difficult to build an ethically grounded, albeit non-nationalistic, sense of nation. The prospect of an agreement between the two, if any, existed on a different plane. As recently as the 1970s, when precisely such an agreement appeared to be feasible, the scenario envisaged by at least some of its major protagonists 'was not to obtain a physiological dialectic in Italian democracy, between forces homologated within the system, but, on the contrary, that of building a new society resulting from the encounter between two worlds, the Catholic and the Communist ones' (Scoppola, 1997: 393).

However, what weighed more heavily in the development of Italian democracy, nailing some way or another citizens to their separate allegiances, was the impossibility of alternate government, which has made Italian democracy a 'stalled democracy'.

In fact, with the Yalta agreements in 1945, Italy found itself belonging to the Western bloc, while having at the same time a powerful Communist party – the strongest in the West – which, however, had no real chances to come to power and create a turnover in the government.

Hence, while the country strived to resume its position on the international scene (Italy joined the United Nations in 1955), its sovereignty was hampered by the impossibility of an alternative government, which affected the very nature of democracy.

With the passing of the years, at the beginning of the 1960s, the governing majority was expanded to include the Socialist party; but this did not extend to the entire left. In the mid-1970s the so-called historic compromise between Catholic and left-wing forces was explored, and went as far as granting 'external support' by the Communist Party (PCI) to the government, but the hypothesis of a more direct involvement of

the Communists was not realized. Notwithstanding the consolidated presence of PCI in local governments, the further step of full participation in the government of the country seemed to be still impossible. As, however, a partly cooperative dynamic existed, there came to be a peculiar situation of ‘consociate democracy’ as it has been sometimes called, in which many agreements could be found, but with no realistic perspective of an alternation in government.

This allowed the country to be governed without forcing those international equilibriums that had proved themselves inviolable, but was obviously negative for democratic dialectic. The majority forces did not fear to be unsaddled and be passed on to the opposition; the opposition, in turn, was not actually asked to elaborate a realistic and organic alternative policy at national level. A possibility of alternation was only envisageable when the post-war equilibria changed, as late as the end of the 1980s. Amongst the many consequences of this manifestly distorted situation, many important ones concerned education.

The Role of Education

Immediately after the armistice (1943), the crucial role to be played by education in the reconstruction of the country called the attention and the action of the Allied Control Commission, which, however, never pushed its action too far. Namely, Carleton Washburne committed himself, involving Italian educationalists as well, to the elaboration of curricula for primary school (adopted in 1945) which were based on the notion of a democratic formation of citizens. Later on, at the time of the drafting of the Constitution, the school was assigned a relevant role, but debate in the Constituent Assembly mainly focused on the space that the new Republic should grant to private schools, which in Italy were almost exclusively Catholic. Once again the educational issue revolved around the relations between the State and the Church. After a complex debate (Palomba, 1985; Ambrosoli, 1982) an agreement was reached whereby private citizens and bodies were free to establish schools, but with no right to State aid. ‘Organizations and private citizens are entitled to found schools and educational institutions, with no charges for the State’ (Article 33 of the Italian Constitution).

After the task of the Constituent Assembly was completed, for almost a decade left-wing opposition parties did not include education among their political priorities (Canestri & Ricuperati, 1976; Semeraro, 1996; Ventura, 1998). In the 1950s in Italy schools were under the control of the majority party, the Christian Democrats, whose ministers managed them without introducing significant reforms, but rather through constant administrative actions (so-called *leggine*, i.e. by-laws) which aimed at maintaining a certain balance, ensuring control over state schools while granting private ones all the space that could be allowed in compliance with the Constitution.

In that period, the school system developed rapidly. In the decade 1951–1961, the number of students and the rate of participation in lower and upper secondary schools doubled. The growth, notwithstanding all its imbalances, corresponded to a moment of intense and quick development, where the quantitative extension itself brought about an enlargement of the social participation to education, thus showing also a qualitative

improvement. After a period of 15 years, however, the need to plan the development according to a socially more adequate model raised the problem of a more advanced reformism, following the international trend at the beginning of the 1960s.

It was the moment of the so-called left turn, which brought about, in December 1963, the first government including the Socialist Party. The entry of the Socialists in the institutions softened the contrast between the representativeness of the institutions themselves and social reality, while still fully respecting the basic features of the system, that is of a State of liberal structure dealing with the social ethics of a large part of the Catholic forces, and without any direct participation of the Communist party to the government.

This shift from a static situation to a more dynamic period of discussion and debate involved many fields – including education – in a ‘reformist’ perspective. This project, however, never quite succeeded in coming into being (CENSIS, 1970).

One of the greater obstacles to the development of authentic reformist action was undoubtedly the difficulty in interpreting univocally the concept of reform itself. In the 1960s and 1970s the ‘meliorist’ hypothesis intertwined with structural reform ones, which were aimed at radical transformations of the system, in order to overcome the bourgeois nature of the State and of its social provisions. So, even if the ‘revolutionary’ perspective as such was no longer on the agenda of the left-wing forces, it was replaced by the call for ‘structural reforms’, which were often burdened ideologically with revolutionary meanings and intentions.

In terms of the political proposals and the cultural orientation of left-wing parties, this translated into a framework of reference in which on the one hand the importance of education for greater social justice emerged, and on the other hand the forms in which education presented itself were rejected. In this perspective, the education reform was seen as a ‘tool to put an end to the class organisation of the existing school’ (Ventura, 1998: 193), and school itself as ‘the major battlefield for a different social and economic development’, as it was stated in an article published in 1972 by *L’Unità*, the official newspaper of the Italian Communist Party (quoted in Chiosso, 1977: 75).

The refusal to recognise the democratic legitimacy of any differentiation – seen as the cause and effect of class-based discrimination – was one of the main reasons for the emergence of the myth of a ‘unified school’, the ‘Holy Grail of the left’ (Polesel, 2006: 550), which affected not only the far left, but also many intellectuals and educationalists, who came to share, for different reasons, the ‘comprehensive approach’, intended, in most cases, as a total lack of diversification.

As is known, the role of education in society was one of the key topics in the sociological debate of those years. As pointed out by Benadusi (1984), a positive image of the social role of education – shared by some sociologists who may be labelled as liberal-functionalist, even if from different (progressive or conservative) perspectives – confronted the image of education upheld by those who emphasised that it was an ideological State apparatus (Althusser) and a tool to reproduce the structures and values of capitalist society (Bourdieu), thus denying the meaningfulness and effectiveness of any reform ‘within the system’. However, amongst those who shared a positive view of education from a ‘progressive’ point of view, the positive attitude was not so much towards the present role of the school, but rather on the ‘school-that-could-be’

(Benadusi, 1984: XI). The debate was very lively in Italy, and was not without influence in the actual policy adopted. In a context in which gradual reformism had very few champions, it ended up merging in the demand for global or ‘structural’ reforms of most non-conservative intellectuals and scholars.

With regard to lower secondary education, a political agreement was reached, which led in December 1962⁷ to the passing of a law that, while confirming the constitutional obligation of an eight-year compulsory school, unified the old academically oriented lower secondary schools with the vocationally oriented *scuole di avviamento al lavoro*.

Scuola media unica (unified lower secondary school) was a fully comprehensive structure, whose purpose was to deliver the common basic education required for every citizen, whether willing to continue studying or not. Throughout the years, this ‘comprehensiveness’ was further improved by doing away with some residual optional elements which could suggest the possibility of a choice or selection: namely, Latin courses in the third year, upon which admission to *liceo classico*⁸ was conditional.

Once the reform passed, it seemed natural to start reorganising upper secondary education as well. However, despite the significant number of bills submitted, several decades were not enough to implement a consistent policy at upper secondary level.

These difficulties show the weakening of social consensus when moving up from basic education. The consensus on some basic elements of ‘education for all’ had developed in the nineteenth and twentieth centuries, almost as a ‘social pact’ on what the basic formation of citizens needed to be. In a way, it could be said, that it was the educational implication of the recognition of human, social, and political rights. As discussed above, the appropriateness of a less differentiated lower secondary education system had been debated in Italy since the early twentieth century. Later on, in 1940, a provision – although a partial one – to unify the system was passed by Giuseppe Bottai. Hence, the ground had already been prepared. Unification at the compulsory level had gained a large and solid social consensus, and the change suggested responded to the actual political and cultural level as well as to the socio-economic development of the country, while also meeting the solidaristic approach shared by the major forces.

A further proof that it was possible to find some agreement in order to implement measures concerning the basic levels of education, even on sensitive points, was the creation of a pre-primary State school in 1968, after memorable fights in Parliament.⁹ In fact, until that moment the presence of the State was missing at that educational level, while private religious institutions were largely present, together with a less widespread presence of local authorities. The growth of the public presence was gradual but not slow, promoting a significant improvement and in the end a generalisation of the participation rate (CENSIS). These data concerning childhood education – a subject so rich in cultural and emotional significance – reveal the transformation of Italian habits, attitudes, and behaviours that went together with the social and economic transformations in the second half of the twentieth century.

Conflict arises when dealing with the ways of differentiation within society, the articulation of social classes and types of work, and therefore the corresponding education articulation at the secondary level. In the 1960s and 1970s, the correspondence of the school structure to a social stratification was questioned. There were criticisms

of the sharp differentiations between *licei*, technical institutes, vocational institutes, and teacher-training schools, that were still, basically, the same of the Gentile reform (the ‘organ-pipes chart’). However, notwithstanding the great number of bills proposed, the attempt of putting in place a different structure of the secondary school did not succeed.

Agreement was found in the fact that the situation was unsatisfactory, but the only shared answer to the rising criticism was to abolish some of the existing bonds, virtually without adopting ‘positive’ measures other than experimental ones. This policy was intended to be temporary, but, as the lack of agreement persisted, it was actually long-lasting and brought about profound changes in the secondary school and the university.

In 1969, three separate measures were adopted, which, taken together, caused the abolition of the regulatory framework that previously conditioned the students’ educational future according to the choices made after the years of compulsory school. Such measures included: (a) the so-called liberalisation of access to university, according to which it was possible to enrol at all university faculties, for those who had completed a five-year secondary school, irrespective of the kind of school they had followed¹⁰; (b) the law modifying the procedure for the secondary-school-leaving-examination, extending the qualification of ‘maturità’ to all the secondary school final examinations¹¹; and (c) the law introducing in vocational institutes – until then not considered as proper secondary schools – some experimental courses intended to allow students to get a five-year diploma, called ‘maturità’ as well,¹² therefore allowing them university access.

All this brought a profound transformation of secondary education. The three measures taken together led to a substantial equivalence between the different study courses, in terms of further educational opportunities, duration of the course and value of the final diploma, thus transforming the prospects resulting from the attendance of a given school, even without a reform of its articulation and contents. It can be observed that, in a way, these measures brought to the highest point the trend towards the abolition of dead-end courses in the school system – with the ensuing effect of de-professionalisation of the system itself – that had periodically been adopted in the history of Italian education policy. As was the case before, it was possible to detect in this action the double intent to meet the aspirations for sociocultural mobility of middle and working classes and to provide ways to absorb jobless secondary-school-leavers.

Admittedly, these were intended to be temporary choices, a ‘breach’ in the old school system, not meant to last. However, the egalitarian frame was desired, and was intended to indicate the direction to be followed to build a new school: but a positive consensus on this issue was not found – and is still hard to find.

However, even if an ‘organic’ reform of the upper secondary school was not achieved, innovation, sometimes relevant, was introduced through several partial measures. To quote a perceptive comment by a non-Italian author, ‘the political landscape of Italy is such that developments at the margin are often the only kind which can be effected, and, therefore, such changes are often of a significance which may surprise the foreign observer’ (Polesel, 2006: 552).

A relevant role has been played by experimental courses that the schools were allowed to create following a law passed in 1974. At the upper secondary level, these

courses offered an opportunity to concretely test many of the emerging reform hypotheses. Actually they have represented permanent innovative features adopted by the schools rather than ‘experimentations’.

In the ensuing years their number had grown, also due to rules that were passed in favour of school autonomy. Consequently, in an essentially unaltered structural framework, many initiatives have been blossoming from individual schools (OCSE-MPI, 1983).

In a later period, there was an attempt at the central level to ‘promote a systemic innovation in a whole cycle of post-compulsory education, even without a legislative framework of reference’ (Niceforo, 1990: 47). An *ad hoc* committee (*Commissione Brocca*, after the name of its President) was established in 1989, with the task of elaborating and proposing new curricula for the first two years of post-compulsory education, aimed at the creation of more flexible learning paths in classical as well as in technical schools. It was once again the administrative way of promoting and managing innovation – and it ended up, if not in a ‘systemic’ change, in more innovative ‘experimental’ courses being permanently included in the system.

Besides the thorny question of upper secondary school, however, in the decades here considered several provisions were adopted about different aspects of the school system. One of the main principles inspiring the action was still the egalitarian principle, together with a strong trend towards participation at all levels. To this overall inspiring *motif* corresponded several measures, from the integration of the handicapped in ordinary schooling to the adoption of new evaluation procedures,¹³ from the liberalization of the university entrance to the enlargement of social participation in the school government.¹⁴

Most of the measures did meet highly sensitive problems. Their main limit lay in the fact that, if on the one hand they addressed concrete questions, on the other, very often they were once again implicitly referring to a school-that-could-be, in a society still-to-be-built, thereby implying a global reform of the educational system which by then was clearly not very realistic. No wonder then if in the end they turned out to be disappointing and fragmentary, being the result of a combination of radical spurs from the bottom and a lack of clear political decisions (Benadusi, 1989).

Still, it has to be considered that, in the Italian context of the 1970s, the illusion – the utopia – of ‘another possible world’ lingered on, sometimes influencing the institutional policies and generating, in some dramatic moments, subversive hypotheses, which fortunately in the end were always belied by facts. Education has to be seen against this background.

Italy After 1989

In more recent times, the egalitarian approach, tied to a radical idea of education and oriented to ‘another-possible-world’, was deeply affected by the changes that took place in the 1980s and most of all in the last two decades. During this period, in Italy as elsewhere the keywords have been quality in education and a need for an external evaluation of the effectiveness of education and training, in the context of a European and an international setting which was very demanding in terms of efficiency and competitiveness.

To fully understand the nature and the meaning of the change the Italian society and education had to face, we need once more to go back to consider certain Italian peculiarities in the rapidly evolving international context, particularly regarding the consequences of the fall of communism.

Italy was much more affected by the fall of the Berlin Wall than most of the other western countries; the end of bipolarism shattered its delicate equilibrium of 'frontier' country, which was heavily conditioned in its democratic dialectic. As Lepre noted, 'Italy had been a borderland between the two systems, and at the same time it had been internally cut across by the border itself' (Lepre, 1993: 21).

The fall of the Berlin Wall and the disintegration of the Soviet Union put an end to this situation; it was said that the post-war period was definitively over. Thus Italy had to re-arrange its political-institutional dynamics according to a radically changed context, where the composition of the governments did not necessarily have to be predetermined.

The first part of the 1990s saw a great turmoil in political life. On the one hand, there was the redefinition of the name and programmes of the Communist Party (PCI): it became Partito Democratico della Sinistra (PDS) in 1990 and then Democratici di Sinistra (DS), paying for these shifts with a split on its left, which gave birth to *Rifondazione Comunista* – Communist Refounding Party. On the other hand, there was a fall of those parties that had governed Italy for almost 50 years, above all Christian Democracy and the Socialist Party. The ruling elite of these latter parties was overwhelmed by the corruption scandals linked to political financing but the deep roots of the turmoil are to be found in the crisis of the equilibrium that had run Europe and the world from Yalta on, where Italy, borderland between two blocs, was one of the keystones.

It was necessary to redefine almost everything. Amongst other things, the electoral system was changed, giving way to the so-called second republic. Also, the proportional system was abandoned, to adopt a mechanism close to the majority system, based on two main coalitions, even though it allows the presence of different parties within each alliance.

The fall of the former leading parties seemed to open the way to the left-wing ones, legitimated at last. Actually, the period of waiting was longer than it was expected, as a newly founded moderate party, Forza Italia, came unexpectedly to fill the gap left by the recent changes, and won the general elections of 1994, in alliance with other forces. Yet in a short time the coalition split up, giving way to a 'technical government', and the left-wing coalition assumed power with the elections of 1996.

This coalition completed its five years of government, despite the many difficulties and the changing of several prime ministers. In 2001 the right-wing coalition won again; in 2006 the Left came back into power. Italy seemed to have eventually found its way to alternation in government.

However, the transformation of the political forces is still going on. New aggregations and new coalition parties, both Left and Right, are constantly being formed.

Concerning school policies, some relevant points can be pinpointed. The most important one is the renewed need for a wide action of reform, maybe not to build a new society as before, but because it is felt that such a changed society needs to reorganise many of its aspects, including education. Therefore, some reformist features can be discerned, not aiming to bring about a less violent revolution, but trying to fulfil the need to reorganise the educational system to face a changed and continuously evolving society.

The need for major changes in the education system has been invoked virtually everywhere in the last years. The point about Italy is that the country is once again at a crucial moment of state formation. From this perspective, the question of the ‘formation of the citizen’ comes up again, with all the difficulties stemming from the previous and the recent history.

In this dynamic, the European unification plays a most relevant role. ‘Conforming to Europe’ becomes a sort of password. The reference to Europe is used as a strong argument to support reformist measures that are felt to be necessary but which jeopardised well-established equilibriums. ‘Europe’ therefore can help to find a common framework of reference, inside which the ‘new’ Italian identity can take shape.

The Italian School System in the Last Decade

In 1996, for the first time a left-wing coalition came to power that included the Democratic Left Party (*Partito democratico della Sinistra*, born from the transformation of the Communist Party) and with the external support of the Communist Refounding Party. The Minister of Education, Luigi Berlinguer, symbolised this change. He is the cousin of Enrico, who was the Secretary of the Communist Party in the crucial 1970s.

Luigi Berlinguer undertook great interventions in every aspect of the educational system, from school to university, from teachers’ training to the Ministry’s structure, from the relations between public and private schools—which came at last to a legislative regulation after more than 50 years from the Constitution—to ‘maturità’ examination, from school autonomy to the territorial reorganisation, and the reform of regional institutes for educational research (Niceforo, 2001; Berlinguer, 2001). Most measures were implemented; some of them remained in force, even, if with some modifications, during the years in which the political Right governed, while others were abrogated.

What the left-wing did not succeed to implement was a real reform of the school structure. The law for school reform (Law n.30, February 2000) was approved on the eve of the termination of the legislature’s terms of office. During the electoral campaign the opposition explicitly promised that in case of victory they would first abrogate that law and propose a new and different reform. And so it happened. In spring 2001 the right-wing won the elections, the law’s application was immediately suspended and two years later (April 2003) the new government approved a delega-law¹⁵ to rearrange the whole school and training system, whose first decrees, concerning compulsory school, were approved in the first months of 2004, while the decrees concerning secondary school were passed in 2005. But these measures in turn did not enjoy a long life, being suspended by a Ministerial Decree of the new left-wing government in May 2006.

The present situation is therefore complex, and not easy to describe, as the concrete school reality is an inextricable interlacing and overlapping of measures kept but modified, cancelled reforms, new reforms, some already approved and gradually coming into force, others still to be defined in detail – all this of course interacting with the pre-existing general features of the system.¹⁶ Irrespective of any judgement about the content of the proposed measures, this process clashes with the typical difficulties of a

substantial reformist action, having to deal with many previous situations, overlapping sets of rules and well-established interests, all problems that, to be overcome, need at the same time decision, consensus-building, political will, and competence.

But above all, the dynamics that have been described show how, in the alternation, the ‘separate belongings’ are still strong, or, to be more accurate, are felt and perceived as such. Especially the first leftist government was tempted to use structural reforms in such a harsh way that it recalled the revolutionary spirit of the previous decades, in method if not in content, reforming at the same time all the sectors of the educational system with what has been called a sort of Jacobin approach. Then, as described just above, each further change in government produced an allegedly global upheaval. Actually, the contents of the different measures are far less distant than declared (once again the most difficult issue being upper secondary school) – but still the idea that the alternation is not so much between two ‘homologated forces within the system’ as between different – perhaps even mutually exclusive – conceptions of society is still alive. At least it still cannot be denied altogether even by the most realistic of political forces, which cannot disregard the lingering of attitudes shaped in so many years of ‘stalled democracy’.

More than anything else, this shows the determining influence that Italy’s peculiar position between the two blocs has had over the Italian political and institutional life, and it is curious to see how the awareness of this influence is lacking in most international and comparative studies on education. Yet one of the last walls between ‘east’ and ‘west’ fell 15 years after the Berlin Wall; it was the wall that until recently divided Gorizia, in Italy, from Nova Gorica, in Slovenia. Only the entry of Slovenia in the EU allowed this wall to fall, while still keeping the division of the city in two different states. This can symbolically represent the particular relevance for our country – not always fully perceived – of the transformation of the international set-up.

Notes

1. Decree by which the Holy See on 10 September 1874 gave a negative answer about the possible participation of Italian Catholics in the elections and in general in the political life of the State. The prohibition was attenuated in 1905, and abolished in 1919.
2. The gap was such that in 1866, Cesare Correnti denounced Italy’s ‘unusual record’ in terms of number of secondary schools and students compared to other countries, while it ranked last in terms of number of popular and primary schools, despite its highest rate of increase in the demand for these schools (Barbagli, 1974: 69).
3. The original text of *I Miei Ricordi* by Massimo d’Azeglio was only brought back to light in the years after the Second World War. That historical and philological episode cannot be dwelt upon herein, but see Soldani and Turi (1993: 17) with particular reference to the sentence quoted above.
4. Rather than one text, it was actually a set of provisions – passed between the end of 1922 and the middle of 1924 – which, however, responded to a consistent design and are usually considered as a whole as the ‘Gentile’s Reform’. The reform is normally dated 1923, the year when most of its provisions were passed.
5. Upper secondary school with an emphasis on science subjects.
6. When the Fascist regime showed its nature more clearly, however, many intellectuals who had first supported it moved away from it – like Lombardo Radice himself.
7. Law 31.XII.1962, n.1859.
8. Law 16.VI.1977, n.348. ‘Liceo classico’: upper secondary school with an emphasis on humanities.
9. Law 18.IV.1968, n.444.

10. Law 11.XII.1969, n.910.
11. Law 5.IV.1969, n.119.
12. Law 27.X.1969, n.754.
13. Law 4.X.1977, n.517.
14. DPR 31.V.1974, n.416.
15. A delega-law is a law that defines the general criteria, delegating the government to emanate specific measures for their practical application.
16. In this situation, it does not seem worthwhile to try giving a description of the system at the moment of writing, which would certainly be more than obsolete when the text will be published. The best reference is to Eurydice data, especially the accurate and frequently updated National Summary sheets.

SOCIAL CHANGE AND CONFIGURATIONS OF RHETORIC: SCHOOLING AND SOCIAL EXCLUSION–INCLUSION IN EDUCATIONAL REFORM IN CONTEMPORARY SPAIN

**Miguel A. Pereyra, J. Carlos González Faraco,
Antonio Luzón, and Mónica Torres**

History and Politics in the Educational Policy Formation of Contemporary Spain

In the last quarter of the twentieth century, Spanish education experienced a full historical cycle closely related to the profound political change that the country experienced during that period of time. The 1970s witnessed the decline and definitive disappearance of the General Franco dictatorship. Immediately after his death in 1975 a process of political transition commenced that was complete but peaceful and based on the accord of the most relevant political parties and social groups. The first fruit of this process was a new Constitution, which was approved by universal suffrage in 1978. This Constitution established a new political regime that is a parliamentary monarchy, similar to those of some other European countries. Accordingly, in 1986 Spain was admitted as a full member of the European Union. For the first time in the history of the country, an ambitious project was undertaken to decentralize the national territory, which resulted in its division into autonomous communities with a significant degree of self-governance (see Judt, 2006, 516–523, for a brief but effective historical narrative of the events of this period).

To these and other political changes, one must also factor in a process of rapid and relatively successful modernization that had just begun in the late 1950s, after the most authoritarian years of the regime, in which Spain began a new era with its “economic stabilization plan” of 1959 supervised by the World Bank, and during the 1960s through the so-called Economic and Social Development Plans (created following the French model of “indicative” economic planning of the postwar era, and technocratically accomplished by a leading elite of high-level civil servants linked to the Opus Dei) (Balfour, 2000). With the advent of democracy after General Franco’s death, the modernization processes accelerated, after the signing of the so-called Social Pact of La Moncloa by the political parties and trade unions of workers and entrepreneurs, with significant consequences for all aspects of the social life of the country. During the 1990s Spain succeeded in situating itself among the most developed countries of the world, experiencing excellent economic indicators and a significant transformation of

social structures and lifestyles (see Puelles, 2000). In the field of education, a number of major reforms were promoted by a succession of governments of distinct ideological orientations. Obviously, much of this phenomenon is similar to what occurred in other Western countries. What distinguishes the Spanish case is the historic *acceleration* of these processes in that country (see McNair, 1984; Boyd-Barrett & O'Malley, 1995; Bonal, 1998; Escolano, 2002; Cuesta, 2005).

Our objective in this chapter is to analyze the politics of education during this crucial period, but we will focus attention particularly on what was the last great reform of the twentieth century, that which was proffered in 1990 by the Socialist Party during its first phase of governance (1982–1996). The effects of this reform persist to this day, the socialists having returned to power following the Madrid terrorist bombings of March 2004. In this sense, our “historical” remarks are really quite contemporary. Our intention is not so much to describe accomplished deeds, but to analyze the interpretations, the images, and the assessments that distinct social actors have applied to the consequences of this socialist reform. Principally, we will analyze their discourse about the impact that these changes in the governance of education have had on processes of social integration and exclusion. It must be remembered that from the start this reform was grounded in a powerful social rhetoric dominated by such expressions as “equality,” “democracy,” “participation,” and “innovation” (see Gramigna, 2006 for a discussion of “the myth of innovation” in contemporary educational reforms).

But let us briefly return to the beginning of this historical cycle, to the final phase of the regime of General Franco. From the 1960s the rejection of the dictatorship gradually grew as it came to be regarded as absolutely illegitimate and anachronistic in the contemporary European context (and Spain soon applied for a preferential relationship or agreement with the European Economic Community after its creation in 1957 – a complicated issue because of the authoritarian status of the regime – which was only granted after 1970). This attitude of rejection extended throughout the university and the labour communities, both of which were clearly conscious of the fact that Spaniards did not have access to the most elementary political rights. Yet, together with them, there were other elements of society that had accommodated to life under the Franco regime, a situation that contributed to a certain relaxation of political repression, and, above all the manifest economic development of the country in those years, which ended with the transformation of a predominantly rural into a modern industrialized state and whose standards of living approached that of most advanced European countries (the annual economic growth of Spain during the 1960s was one of the highest among all OECD countries). On the other hand, the same government of General Franco, in this final stage of the dictatorship, was aware of the waning relevance of many institutions in the face of the changes being experienced by Spanish society. Among these were the educational institutions. As a result, the regime promoted a grand educational reform in 1970 by means of a General Law of Education (*Ley General de Educación*), the greatest transformation imposed on the Spanish educational system since the middle of the nineteenth century and opportunistically presented as the next step of the implementation of the previously quoted Economic and Social Development Plans. Likewise, the new reform led by the Opus Dei shown an almost thaumaturgic modernization of Spain sought to link a seamless, reactionary, and Catholic antiliberalist

sources of the regime to a modern “Europeanized” Spain (Saz Campos, 2004, and for the analysis of the role played by the *Opus Dei*, Casanova, 1982, 1983). From this strategic decision of one of the last Franco administrations was born the fundamental features of the present Spanish educational system.

Through a technocratic reform conceived under the premises of the human capital theory of the 1960s spread out by previous reports conducted by the UNESCO, OECD, and the World Bank (by which education began to be considered in Spain as investment and consumption, and not only skilled workers, middle- and high-level technicians were necessary for developing the country but an overall better cultural level of Spanish people), the Franco regime attempted to adopt a progressive rhetoric of social change in order to sustain and extend as much as possible its increasingly precarious national and international credibility and its real deficit of political legitimacy at a time when the regime was seeking to be admitted to the European Common Market. In this sense, the reform enacted in the General Law of Education (*Ley General de Educación*), promoted by a pioneering program of mass-media publicity, aptly characterized as a “political spectacle” (Edelman, 1988), sought to diffuse a new language of social change by means of a mystified articulation of social modernization (Ortega, 1994). This process can be understood as an example of the process that Weiler (1983) called *compensatory legitimation* in his analyses of educational reforms (see Morgenstern de Finkel, 1991, 1993). As one of the leading ministers of Franco’s regime indicated in his very important memoirs, referring to a memo passed to him by a colleague while the ministers were discussing the problematic situation arisen by the revolts held in the Spanish universities just when 1969 was beginning, more than a year and half before the General Law of Education was enacted: “this is sinking by the hour. Let us think what to be done ... [because] we do not have to be an augur for viewing the failure of repression” (López Rodó, 1991, 386).

Ironically, this feature of the political strategy of the 1970 reform has not received adequate analytical attention in Spain. However, this reform ended up profoundly altering a traditionally elitist system, institutionalized a distinctive and effective comprehensive school system inspired by the Scandinavian model through the emerging processes of educational globalization undertaken by OECD and UNESCO recommendations, and brought about wide-ranging curriculum reform.

After the death of Franco and in the context of the so-called Transition to Democracy (*Transición a la Democracia*), numerous educational reforms took place that exposed the fundamental disagreements underlying the diverse political, social, and professional constituencies affected. The parliamentary debates concerning the new Constitution were particularly acrimonious when addressing educational issues. Generally speaking, the political right supported the position of the Catholic Church, which had traditionally exercised an extraordinary influence on public instruction in Spain and still controlled a great part of private education. Leftists sought to increase the control of the state over schools. They also favoured encouraging the participation of parents in the governance of educational institutions and they sought to enhance the equality of the system through programs of social integration. For the left it was essential that political democracy translate into educational democracy. As had already occurred in the nineteenth century and during the Second Republic of Spain (1931–1936), people

began to speak of a “school war.” This tense educational climate persisted throughout the following political stage and, in reality, continues to this very day.

In 1982 the Socialist Party overwhelmingly won the general elections. It was a historical milestone given that this party, which had such a decisive role during the Second Republic in the 1930s, reemerged in the 1970s after a long period of clandestinity during the Franco regime. A new generation of young socialists, headed by Felipe González, was to maintain control over the Spanish government until 1996. Soon after assuming power, they established the *Ley Orgánica del Derecho a la Educación*, or the Organic Law of the Right to Education (LODE, 1985), that developed some essential points of the Constitution of 1978. This extraordinarily polemical law explicitly consecrated “the principle of participation of the members of the educational community” as a key factor of educational policy and the State established controls to prevent discriminatory practices that even applied to private schools. As could be expected, the new regulation of educational institutions was harshly criticized by the proprietors of schools and by some parents’ associations in the private sector. Protests were frequently articulated in the streets and in the media and parliamentary procedures for the approval of the law were slow and tortuous. The defenders of private education, among them the Catholic Church, argued that this law represented an unacceptable interference of the State with the rights of families and the liberty of instruction that were also recognized in the new Constitution.

In 1990 the Socialist Party undertook a new modernization of the Spanish educational system – the first since the reform of 1970 – that would put an even greater emphasis on the comprehensive nature of the school by avoiding defined tracking policies (Bonal, 1998; Puellas, 2000; Fernández, 1999, 2003). This new reform was legally formalized as the *Law of General Planning of the Education System* (LOGSE, 1990). Obligatory schooling was extended to the age of 16 and wide-ranging changes in the curriculum were undertaken. Among the most important of these changes were the introduction of the so-called cross-curriculum areas of study and new fields of social learning concerning gender, multiculturalism, and the environment (see an overview in English in Boyd-Barrett & O’Malley, 1995).

The curriculum designed by the Socialist reform was theoretically based in cognitive constructivism and defended the creation of a new type of school culture and a new educational community through the development of appropriate moral values and attitudes (in fact the reform was designed by leading professors of psychology of education – and not from pedagogy as it is frequently thought – at the level of a *total psychologization* where language was consciously saturated “with constructivism, aptitude, psychological diversification ... but not social classes, racism, cultural bias, school failure.” See Torres (2007, 121) and Varela (1991) for a provocative understanding of this reform as a reform designed for the middle classes, by which we arrive at a real triumph of psychological pedagogies focused on the learner and the psychological significance of the content and procedures administered by teachers being converted to animators, counsellors, or coaches basically). With the increase in conflict in schools, “living together” gradually became a priority focus of interest, as would also occur with “multiculturalism” attendant with the growing influx of immigrants, mainly from Africa, Latin America, and Eastern Europe. In the second half of the

1990s, the number of Latin American immigrants in Spain doubled, while the African immigrants tripled. In these circumstances, “educating for values” and “intercultural education” came to be well known and frequently discussed subjects in a curricular context that the Socialist reform attempted to “flexibilize.”

Nevertheless, after an initial phase of intense pushing for reform during the 1980s, during which the rhetoric of the old ideological traditions of the left dominated, the Socialist Party gradually diminished its enthusiasm for some of the reforms initially championed. Pragmatically, the governing socialists began to take into account that the emphasis that they had placed, for example, on social participation was much closer to the utopian ideas of the 1970s than to the responsible realism that, they thought, ought to characterize the action of a governing political party. These types of arguments were deployed at times to justify what came to be regarded as a necessary pragmatism and some socialist leaders came to reconsider some of their earliest proposed reforms. Not a few social critics lambasted the socialists for their evident abandonment of the socially advanced and pedagogically reformist politics that had characterized their first years in government. For the most severe but sound critics this shift represented a surrender of principles in the face of the neoliberal currents that were beginning to inundate the educational arena or “market” in the rest of the world (see Rozada, 2002, for the case of the Spanish educational reforms introduced in the last decades).

In 1996, after their victory in general elections, the conservative Popular Party formed a new government that immediately began to redirect the main aims of the Socialist education policy (a national evaluation of the educational system was conducted for the first time in history; see García Garrido *et al.*, 1998). After obtaining another majority in the 2000 elections, the Popular Party pushed through Parliament the Law of Educational Quality (*Ley de Calidad de la Educación, LOCE*, 2002), which openly questioned the overall foundations of the previous reform, introducing some substantial changes in the obligatory period of education that have for the most part not been implemented (see a recent analysis of this period and about the debate of this law in Rambla, 2006).¹ In an atmosphere in which the predominant impression was one of chaos in the classroom, with insistent calls for recovery of lost authority and order, some measures began to be taken to improve the situation.

As noted above, the analysis which follows centres exclusively on the application and development of the socialist reform under the various governments of Felipe González (1982–1996), although the LOGSE also remained legally in force under the first government of the Popular Party (1996–2000). During the González era, the Socialist Party attempted to build a comprehensive, integrative system to combat the social inequalities in Spain at that time. In these circumstances, the development of a comprehensive school was seriously hampered, as shown by many diverse studies that focused on the lasting consequences of the rhetoric of “social redemption” that accompanied the Socialist reform of the 1990s (Peruga & Torres, 1997; San Segundo, 1998; Carabaña, 1999; Echevarría, 1999; Rambla & Bonal, 2000; Sevilla, 2003).

In this context, the result was not so much a weakening of a dual educational system, but, indeed, its reinforcement, thus adding another indisputable source of social exclusion to factors such as race, gender, or social marginalization. We are, of course, referring to the progressive devaluation of the public network of schools in favor of

Figure 1. History, politics, and educational reforms in contemporary Spain

the private sector. At present more than 35% of the school population (in gross figures closer to 50% in the more developed regions such as Catalonia or the Basque Country) attends grant-maintained private schools, many of which depend on the Catholic Church and its religious orders. Public schools are becoming the schools of the least socially and economically privileged children, while grant-maintained schools monopolize the middle classes. This parallel system, traditional in Spanish education

(a general historical account in Boyd, 1997), is being reproduced in the public system itself, as a possibly spurious consequence of the principle of autonomy. Particularly in urban areas, the public educational network is gradually breaking up in a manner that reflects the geographical location of the center, the pupils' social origins, and the duration of the school day. There are clearly marginal public schools used only by families living in the vicinity. On the other hand, there are prestigious public schools in extraordinary demand by both teachers and families, even though they may live some distance away. In practice, the two represent utterly different institutional strands. In general terms, the immigrant population living in suburban or poor areas makes use of the lower-quality centers, thus adding to their already complex problems (see Fundación Encuentro, 1997, for one of the first empirical analyses carried out about this problematic situation, and Rambla, 1998; Olmedo Reinoso, 2008 & Abrantes, 2008, for most recent debates and data). This ongoing process in the Spanish educational system is one of the major sources of social exclusion (see McAll, 1995, and Green, Preston & Janmaat, 2006, ch.5, for the conclusion that new choice-based reforms introduced in the last decades may undermine educational equality, and thus social cohesion), as it is also embedded in the context of a too weak Spanish educational equity policy (see Calero, 2007).

Taking into account the ever-increasing complexity of these processes (see Figure 1 for a chronological synthesis), we can say that social exclusion is the result of the interactions (with all their deficiencies and distortions) among different classes of social actors, rather than an end state or condition attributable to a particular population or group. In this sense, social exclusion can be understood in an increasingly diverse manner, as a processual, accumulative, multidimensional social reality operating in different social spheres, most particularly in education (Littlewood & Herkommer, 1999; Moreno, 2000, ch. 1; Goguel d'Allondans, 2003). In this text, we analyze the presence of this and other key concepts in the discourse of various educational actors² on the construction of the Spanish school of today – how they imagine it and its problems – taking the reforms mentioned above as our point of reference. We focus on an analysis restricted to the educational actors' images of education, of the school and of the pupils in an educational climate marked by the Socialist reform of the 1990s.

School in the Discourse of Educational Actors

In the context of the neoliberal restructuring of global capitalism, a succession of changes took place in European educational systems in the last decades of the twentieth century. In many cases, such as Spain, more or less far-reaching educational reforms were carried out under “modernizing left-wing” governments. These reforms attempted to explore the possibilities of the post-fordist economic model by reactivating the debate on education in terms of equity *versus* efficiency. In other cases, the precepts of what is commonly known as the “New Right” could be detected in the “creation of a quasi-market within which schools would compete” (Brown & Lauder, 1997, 176; Calero & Bonal, 1999; Barlett et al., 2002).

Without a doubt, behind every educational reform there lies a more or less rhetorically defined political project framed as an effort to construct a new type of citizen

that is only relatively defined, as well as models or images of infancy and the pupil, of the teacher, of the school, and of education. These models and images are also only relatively precise and are subjected to a complex and intense verbal process that brings out the contrasting viewpoints characterizing the various educational actors. Although reforms attempt to present solid models and clear-cut orientations for decision-making, they are often a source of (sometimes hidden) division, dispute, and confusion. Their effects are therefore contradictory and paradoxical. Together with the optimistic projection of the future, nostalgia grows for apparently safer times past. Discourse becomes increasingly fragmented against the apparent unity of the theory.

Particularly in the Spanish case – and in the context of a country coming from a fascist-style dictatorship which constantly and systematically used propaganda and rhetoric for opportunistically conveying its economic and social reforms mentioned before – the use of rhetoric for legitimizing discourses in educational reforms has had a consistent traditional role on the formation of social subjectivity (see Bolívar & Rodríguez Diéguez, 2002). Keeping in mind that a common function of communication is to persuade, and conceiving that “rhetoric, like other modes of discursive organization, is not simply the organization of speech [but] the organization of persuasive discourse is simultaneously the organization of social ‘things’ and social practices” (Valverde, 1990, 67), the whole educational reform process during the Socialist government ended up as so much “flowery rhetoric” making use of constructivist psychological language that overstates the protagonist role played by teachers. The reform process began in the early 1980s with a rhetoric that only developed consistency with the ascension to power at the ministry of some leading educational psychology scholars (when the conservatives eventually replaced the socialists, the Popular Party at first continued making use of progressive, albeit less “flowery”, rhetoric for concealing their reforms which favoured a more selective educational system, and increasing private education).

One of Spain’s most influential educators, an executive adviser to the Minister of Education during the first Socialist government and a frequent consultant in successive Socialist governments, eloquently expressed this development:

The leftist discourse of the Socialist governments diluted quite quickly into a gallinaceous politics of low-level flight. ... The serious politics of the medium and the long-term was replaced by schooling renewal jargon that did little to reform the system, serving more as a placebo than anything else. Instead of tackling reform issues of great import (improving teacher education, developing the teaching profession, enlarging school facilities, combating inequalities, etc.), they spent dozens of thousands of millions in taking meetings and in filling the administrations with “liberated” teachers [i.e., faculty who took leaves of absence from school work to assume official posts at the Administration] who wrote scripts and curricular material intended to translate the language of reform for other teachers. ... A psychological discourse became policy and orthodoxy effectively expelling any other approach. A real political shift was replaced by a clever waffle that gave teachers the illusion of movement that was, in fact, a device for maintaining the status quo.” (Gimeno Sacristán, 1999, 32–33)

The LOGSE (*Law of General Planning of the Education System*, 1990) appeared in the narratives of most of the actors as a turning point in the history of education, both for those who considered themselves its ideological framers and for those charged with its practical execution. For the latter, however, this was a reform imposed on them from above, in the context of a hierarchical, vertical organization in which their voices had scarcely been taken into account. Even considering their differences of viewpoint, many educational actors shared the idea that the school, or rather, education, represents the future of any nation, despite the continuous fractures and disjunctions occurring between the design of educational policy and its effective implementation. They continue to place their confidence and hopes in the school as a means to achieve a more just and plural society and a better world. We can observe the construction of “narratives of salvation,” that is, narratives that link the self-actualization of individuals in the schools with the capacity of the nation to accomplish its “natural” destiny in the areas of economics, politics, and culture (Meyer *et al.*, 1997; Popkewitz, 1998). This “generalization” from the individual is explained in a historical context of an existing “world culture” dominated by broad processes of rationalization that have finished by generating guidelines for the universalistic interpretations of a scientific-rational order and, as a result, symbolic standards of behaviour (Meyer *et al.*, 1987; Meyer & Jefferson, 2000; Meyer & Ramirez, 2000).

School and Social Change: Between Confidence and Scepticism

The school has changed, just as all of society, of which it is the reflection, has changed. In this sense, the school is seen as part of a structural entity – the social system – strictly conditioned by an economic and political hegemonic model. The school is, thus, an extremely dependent social agency, whose obvious changes are not homogeneously evaluated by the different educational actors, some of whom question if it really has changed, i.e., if the reforms are ultimately no more than an illusion.

However, the social importance of the school, as a powerful agent of socialization is persistently highlighted and approved. Just like the family, the school provides the necessary resources for establishing a degree of rationality and progress in the life of individuals and the social community. This image of the school in close association with society and its development is not new, but seems to have become more relevant. Even the traditional social leadership of the family in children’s education is now shared with the school, in which are placed desires and hopes as fundamental spaces for the construction of the social identity of the children.

Together with this predominantly social discourse, we may also consider other narratives linked to it, such as the creation of individuality, the loss of social capital, or interpersonal trust. As some authors have already pointed out (e.g., Putnam, 1995; Torcal & Montero, 2000), today’s democratic societies all suffer from both increasing individualism and a lack of social trust, which is a feature that should be typical of this type of society. So, beyond the view of the school as a socializing or social institution, there emerges this other discourse of the “rebirth of individuality” that is very widespread in the European Union (Lindblad & Popkewitz, 2001). Indeed, although *globality*, understood from a social viewpoint, and *individuality* are inexorably linked as two sides of the same coin, we noted a striking silence on such a major question in

the entirety of the discourse of the actors. None of them make the slightest reference to global processes, which, together with local identities, could be shaping key aspects of contemporary school and society, such as the type of citizen we want and what is required of the school. Despite being omnipresent in the media, globalization is here surprisingly absent.

Combating Inequality: The Reform as Social Imperative

The Socialist educational reform of the 1990s was a historic necessity in order to transform and modernize the Spanish school and thus respond to important social demands, such as equality of opportunity, attention to diversity, integration of differences, and the reduction of exclusion. The vast majority of actors coincided in their affirmation that the school had changed in these respects as a result of the reform.

The educational model is now ruled by an integrating concept following principles such as the defence of equality and respect for diversity. These principles extend to connotations of “transcendental sign,” as Derrida would say, i.e., ideas blessed by success and not questioned or problematized by anyone, at least until their implementation is analyzed. For many, the school is even seen as a social avant-garde, driving and protagonizing changes that go beyond the strict space traditionally assigned to it. This rejuvenates it as an institution and provides optimism through the confidence placed in it by society, despite the inertias and resistance attributed to the teaching staff and educational administration. Naturally, these promising images contrast with the more nostalgic and sceptical images of the teachers and some sectors of civil society.

On the basis of the differences of opinion transmitted by the various narratives, we can, however, conclude that they all corroborate the need for the reform as a means of adapting the school to social change and as a means, as well, of constructing a new, competent, and competitive citizen ready for the times in which we are living. Once again, the main actors present the school, and more precisely the education reform as the image of a history of progress or salvation incarnate in the representation of this new citizen. It is curious, and paradoxical, that these “stories of salvation,”³ as commonly occurs in mythical projections, tend to be linked with myths of origin, with former and better times that are ultimately remembered with nostalgia. We shall return to this question.

The School, Compensator of Inequalities or Creator of Subjectivities

There is a general insistence that the school should pursue the personal development of individuals in order to enable them to respond independently to the challenges which the complexity of today’s society might present them with. Schools should produce students who, above all, have their own minds, are critical, and are able to search for and manage information. At the same time, the school must propose the integration into the system of those pupils who were previously forced to leave it without finishing their studies for whatever reason (accumulated failure, the need to work, etc.) or were forced to opt for devalued vocational training in a dual system in which social and academic prestige were only found in the studies leading to the university. The educational reform of the 1990s

thus represented a new horizon of democratization for a system that was opening up to diversity, reevaluating vocational training and encouraging new style of learning.

However, the school is not a panacea. The high degree of hope aroused by the reform weakens when it is observed that the school cannot solve all the problems created by society, nor attend to all of its demands, which in many cases are exaggerated or unattainable. This “realism” contrasts with the optimism implicit in the legislative texts and discourses of the same political actors at the inception of the reform process ten years previously. It is extremely difficult to generalize the educational changes originally set out in the norms to culturally and economically deficient groups and communities. The actors, even when displaying their faith in the equalizing power of the educational system, seem to express more the desire than the conviction that the school will satisfactorily solve the educational consequences of human diversity and social inequality.

The discourses built up by educational actors are rather more than the expression of personal beliefs and experiences – they establish categories and classify and normalize the functions attributed to the school. Behind the words of praise for its function as an institution, there may lay hidden interpretations that one way or another dampen these initial, complacent images. To defend a compensatory school means, at bottom, benevolently to legitimize differences, even though it is a commonly accepted opinion, almost a stereotype, that the school, especially when it is public, is a hospitable space and that only society marginalizes and excludes. There is a clear conception of social inclusion–exclusion expressed in the discourses of most of the educational actors which suggests that their reason systems do not realize that the school also creates barriers through which it distributes its subjects.

Indeed, we can see how the discourses examined here implicitly and explicitly suggest norms and resort to categories associated with a number of resources designed to improve the school. However, at the same time, they establish normalizing mechanisms steeped in the ambiguous, fluctuating rhetoric of “quality,” designed to inoculate the pupils with the idea of success or failure. Some categorical images, to which we shall return later, sharply confirm that, in spite of egalitarian rhetoric, the school continues to represent a classification space aimed at producing the citizen of the future. Proof of this are the persistent attempts to fit the student into an established social order whose characteristics are reflected in certain nostalgias pervading educational thinking that prevent the school from forging an imagery capable of reformulating itself into something new.

Order and Discipline, Myths for a School of Nostalgia

Nostalgia, of course, is the clearest sign of a process of cultural acceleration, which comes full circle in a short time and, therefore, implies a certain sentimental return to origins. There has been a truly spectacular generation and expansion of changes in the European school since the 1960s (somewhat later in Spain than elsewhere). These changes, based on a generalized reforming rhetoric, have produced a feeling that we were entering a new historic stage, have reshaped the identities of the educational actors and have introduced disorder into the system while waiting for the changes to

gradually be assimilated. However, it is well known that, for example, an appreciable sector of secondary school teachers has embraced an attitude of regret for lost “quality” as a form of resistance to the changes that have occurred in this stage of schooling. This nostalgia has reproduced discourses well established in the educational tradition, such as the question of personal effort and other similar values that the Popular Party’s *Law of Quality* (2002) foregrounds. The fixation with so-called tradition (even the invention of traditions as a cultural strategy) is a relevant characteristic of late modernism and a symptom of confusion in the face of change (see Giddens, 2000). In their statements, teachers even recall the rites and ceremonies of the school of old when the distribution of roles and rules of behavior were set out and clearly defined for the different groups present in the school community (González Faraco, 2002). When traditions fade or are questioned, as in contemporary education, our perception of the ego is disturbed and, when its identity is unstable, one usually resorts to resistance, escapism, or fixation with tradition to make a present of the past. The widespread theories of teachers’ discontent help to provide “scientific” arguments for these “retrospective” attitudes. Whatever the case, it is true that in this as in many other cultural processes, nostalgia acts as a mechanism to domesticate the new (Sahlins, 2000).

According to a large number of educational actors, discipline, order, and organization are held to be intrinsic values of the school, whose devaluation today may be due to several related causes: the crisis of values suffered by today’s society, the transfer of all of society’s evils to the school, the teacher’s loss of authority and social prestige, scant participation of the family, etc. Behind these imputations we can detect memories and cultural representations that could play a central part in the construction of a system of inclusion and exclusion (Meyer *et al.*, 1997). The school is still a fundamental brick in the edifice of society, but it must also be acknowledged that the problems of living together in schools have increased, and with them lack of discipline and even violence. The management problems of some secondary schools are increasingly evident. For many actors the extension of obligatory schooling to the age of 16 was a source of many of these problems, particularly in the areas of high social risk.

Much of the actors’ attention is concentrated on the obligatory stage of secondary education because it presents most of the problems. The educational actors’ narratives divide the pupils into two opposing categories: “those motivated to study and learn” and “those without motivation who are bored” and “would like to leave school, but are forced to stay.” This dialectic causes disagreement and tension among the teachers, who claim not to know how to deal with these pupils in a differentiated fashion and therefore criticize or reject the supposed advantages of the integrating model of the reform. Once again, we find an ambivalent, paradoxical, and, to a large extent, broken discourse. On the one hand, we are presented with the vision of an open, comprehensive, egalitarian school that compensates for inequality – a welcoming school with room for all. On the other hand, we hear the discourse of the lamented, peaceful, well-ordered school, built on the model of the ideal pupil, the cosmopolitan citizen prepared to face and resolve problems, the citizen competent in the knowledge and learning society (see Popkewitz, 2007, for exploring today’s historical turn of the changing principles of cosmopolitanism in educational reforms and research designed to produce greater involvement and participation in contemporary societies). In this situation, a central role is played by

the teacher's loss of authority and social prestige, by the disappearance or decline of the teaching profession's vocational character, and by the weakening of the family's educational capacity as a result of changes in family roles, especially that of the mother, mainly because of the increasing number of working women.

In such extremely common discourses, education is seen as a strategy by which to acquire a set of "rules" designed to create a model citizen appropriate to the demands of today's society – what we have called the "cosmopolitan citizen." We have already argued that these narratives incorporate systems of reason that speak of individuals as reasonable, adapted, enterprising people. In other words, they organize a social cartography that rewards some and punishes or excludes others.

Living together is only possible with rules. The increasing weakness of family socialization has made the school the main social institution responsible for setting up a social order governed by rules that inspire confidence because of the reliability of their results. Teachers are given the role of "guide" in the new models of organization, based on efficiency and control in any educational sphere including policy and curriculum. It is not surprising that evaluation is exalted and old concepts such as "conduct" and "behavior" returns to the forefront of educational culture and their decisive influence on the failure or success of the pupils is underscored.

Although some actors recall, in a negative light, the image of that discipline-oriented, hierarchical, authoritarian, and class-conscious school that legitimized profound social inequalities, their discourse continues to be implicitly dominated by the need to recover lost order, symbolic discipline, and their role as director of learning. In other words, a return to the past disguised at times by a veneer of modernity.

Enterprise as a Model for an Efficient School

It has been very attractive for theoreticians of education and the social sciences in general to draw parallels, correspondences, and comparisons between the world of education and the world of business. Many have proposed the application of business principles in the school. No one, in fact, wanted to give the impression of turning back to old product-oriented models, but many of the actors connected with school administration and management, and even Socialist Party members or sympathizers, think that the firm should be the mirror in which the school views itself – as looking to the business practices to bolster its public legitimacy – if it wants to improve its competitiveness and efficiency and not be replaced by other educational agencies.

Some actors apply the idea of "corporative efficiency" to the school because, from their point of view, it would optimize management, increase its members' degree of responsibility, and have a favorable effect on the pupils' learning. Albeit not explicitly, it is a conception that seeks a more efficient school, dedicated to the improvement of results through control and more efficient organization of human and financial resources, independently of, but not contradicting the adoption of managerial models based on decentralization and the autonomy of schools. These principles are usually found in the rhetoric of the reforms we have analyzed, which shifted toward diverse forms of decentralization, devolution, and deregulation as key mechanisms of restructuring. These principles are particularly evident in the school-based management system launched in

the Socialist governments in Spain and continued by the Popular Party after 1996 (for a contextual analysis see Whitty *et al.*, 1998, and Lindblad & Popkewitz, 2004).

The essential function of the school is the formation of citizens, which should be understood as their “integration into the socioeconomic world.” Being a good citizen therefore means being a good worker and a good professional and, in order to become one, the school must provide its pupils with knowledge and skills that are useful in the labour market. However, it cannot be said that this managerial vision of the school is widely shared explicitly by educational actors. Proposals that lead us to think of desirable isomorphisms between school and firm are not frequent either. However, the idea is more commonly held that the pupils are learners in a system that should be aware of, and even at the service of, the labour market. In these circumstances, it does not seem accidental that the so-called technological paradigm (“the official pedagogy” as Basil Bernstein would put it) should predominate in the Spanish pedagogical arena since, at bottom, it helps to legitimize through science these types of efficiency-based postulates.

The discourse of the actors reflects the innovations introduced by the Socialist reform and, through them, the characteristics of the new legitimizing framework of Spanish education. But, as we have seen above, they also speak to the inadequacies, weaknesses, or perversions of the reform process, as experienced in their professional work. These critical discourses diverge, cross, and, at times, coalesce around certain subjects – excessive bureaucracy; the imbalances between public schools and private grant-supported schools; the lack of material and human resources; and other issues concerning teachers, such as work overload, lack of social recognition, and broad discontent with a reformist rhetoric that does not result in action. The never-ending argument about theory and practice is well represented here.

School actors call for more participation in educational decisions, but do not see any structural alternatives on the horizon to facilitate this participation, nor do they provide specific measures that might give back their lost protagonism. Meanwhile, the political actors pass on to the educational administration the responsibility of interpreting and implementing the texts resulting from the reform. They claim that to carry out the changes in organization and operation of the school it is absolutely necessary to have a professionalized head teacher and team to execute the policy of the administration. This does not prevent them from accepting the ideas of community representation and participation in school governance, or even proposing more decentralized models of educational management.

In this context of frank disagreement between school and political actors, paradoxical situations can arise, such as the rapid application of the new school day in Andalusia, which moved from an “all-day” school (with morning and afternoon sessions) to a “half day” (*jornada continuada* from 9 a.m. to 2 p.m.). In this case, the independent criteria of the schools were upheld against the differences between the school community (in favor of a half-day school) and the educational administration (opposed to the idea, as it might prove harmful for pupils from less favoured social layers, with the attendant risk of exclusion) (Pereyra, 2002). The Andalusian administration finally had to accept a decision advocated by the majority of the participants in the governance of each school.

Once again we find a poorly articulated process of normalization, constructed with inadequate criteria, some infelicitous improvisation, and a minimum of equanimity. The

identity spaces of the various educational actors are restricted to their own particular field of view, without attempting to analyze, discuss, or reflect on the broad consequences that the adoption of a specific measure could entail. The decisions are upheld and the arguments justified because they say they are invariably directed toward the improvement of quality in the educational process. But an avalanche of reformative categories, such as decentralization, autonomy, efficiency, progress, and quality colors all of their discourses, which become tautological exercises, with no attempt made either to go further into theoretical questions or to reflect on their own practice.

Inclusion–Exclusion as an Effect of Educational Governance: Hopes, Doubts, and Contradictions

When speaking of governance we are not referring descriptively to the rules imposed by particular administrative measures or social imperatives, but to the rational construction of mechanisms, patterns, and decisions that make up the conscience and thought of individuals. In other words, we understand governance not just as a set of processes of production and distribution of social goods through institutions and personal interaction, but governance is considered here as systems of knowledge that propose “solutions to problems” in social policy and practice. From this point of view, and leaving aside the rhetoric most commonly used in this sphere, the key question is whether and to what extent the school, so often described confusingly by educational actors, constructs or sustains individual and collective criteria of division, marginalization, and exclusion. To speak of exclusion also implies inclusion, for conceptually they are two terms in the same semantic field (although at opposite extremes), but it is also to speak of two different things, as they rarely present a similar level of normalization.

Bearing in mind this link between the two concepts, we shall now try to observe and analyze through the discourse of the educational actors themselves how the process of inclusion–exclusion manifests itself and operates in the school. For the majority, the question of exclusion is foreign to the school environment, where, on the contrary, “attention to diversity,” integration, and equity are promoted.

This integrating image, in which failure is merely a “natural” process or the effect of a cause outside the system, is widely shared as a premise, but takes on very different tones when the analysis probes practice in specific contexts. Indeed, to understand education is to understand its context. As a result, the question of inclusion–exclusion takes on differentiating characteristics and produces divergent discourses. The actors tended to talk of two types of exclusion: “school failure” and “self-exclusion.” The first is associated with pupils with special educational needs and “self-exclusion” refers to students with problems of social origin, such as drugs, alcoholism, delinquency, etc. In any case, it is not the school but society that marginalizes and excludes them. Behind these arguments lies an eminently individualistic discourse that makes the differences seem natural and frees the system of all guilt. The system only has to apply the principles of reason (distinctions, differentiations, and categories of knowledge) that will or will not qualify the individual for action or participation. In other cases, there is some recognition that the school system can exclude, but then exclusion is understood conventionally, i.e., according to the degree of participation in society of the individuals and groups according to certain social standards.

This discourse on the capacity of the school for inclusion or exclusion breaks down around the problem of the duality of the system. A dialectical spiral occurs between those who accuse the private school of selective practices and those who defend the right to establish independently their own educational model. The two interpret the relations between educational governance and social inclusion–exclusion in significantly different ways, i.e., they apply antagonistic systems of reason in an attempt to legitimize their respective attitudes. The result is an involved, fragmented, belligerent discursive scenario.

For some the fight against exclusion should mainly be based on an ethical and pedagogical program centered on an education in human and Christian values and on a dialogue between parents and tutors taking joint decisions about the personal treatment of the pupils. For others, there is no point in limiting oneself to the school if we want to deal with the problem of exclusion, because its origin is above all social, especially social marginality, although we must not forget the excluding effects of educational failure and other personal circumstances. From this point of view, the most suitable ways to combat exclusion should be dialogue between pupil, family, and teacher, the development of attitudes inclined to accept the other, improvement in the family's education, and a cooperative approach with other administrative institutions and social organizations.

Although they are not lacking in scepticism, most of the actors seem to be confident that the school can reduce inequality: schools are, after all, open, plural institutions that receive all types of pupils. In this sense, the school has an important role to play in the consolidation of a more just and democratic society, in which those now excluded would have the chance to participate more fully in all social spheres. This participation could be tried out in schools, but the ultimate responsibility for making it a reality lies with the family. However, for the moment the family's involvement is insufficient, as shown by the low indices of family voting in the elections for school councils.

One of the most persistent arguments found in the educational actors' discourses is the increasing confidence deposited in the school, which runs parallel to the call for the family to again take more responsibility for its children's education. However, among those who state such faith in the democratizing power of the school, there are hardly any with viable proposals for introducing changes in the governance of education in order to tackle problems such as low family involvement in their children's school life, premature abandonment of school, or other situations with potential to cause exclusion. Discursive strategies such as silence, blaming others, or resorting to politically correct statements lead us to think that, behind the expressions of confidence in the democratizing power of the school, there is an implicit understanding that such confidence is merely an illusion.

Light and Shade without Rhetoric: By Way of Conclusion

In the context of a country contemporarily come into being from a long fascistized dictatorship which systematically maneuvered with rhetorical and symbolical illusions of social change without introducing and implementing deep political and socioeconomical transformations, the Socialist reform of the 1990s through the analysis of its actors' discourse appears as an indistinct, ambivalent narration arising out of the gap between a few illuminating intellectual discoveries and darker practical implications. The optimism they express about the social changes occurring during this decade turns to scepticism regarding the changes experienced by the school, which, they understand not to be exclusively due to the educational reforms.

These contrasts can probably best be seen among the teaching staff. In-service teacher training, for example, has improved substantially. However, the social prestige of teaching has declined, the practice of the profession has deteriorated (excessive workloads, hard to accept social expectations, etc.), and relations with the political administration have become increasingly strained. Democratization, autonomy, and bureaucratization have become typical factors in the imagery and narratives of school actors. Despite the fact that the educational reform should have meant greater democratization and autonomy of management, the teachers continuously complain of bureaucratization and the deficient administrative organization of education.

On the other hand, the one essential change in the structure of the system brought about by the LOGSE was the extending of obligatory education to the age of 16, with the subsequent creation of a new stage of secondary education, i.e., a strong drive toward a comprehensive school. However, this decision has led to numerous problems related to the desire of some pupils to leave the system before that age (school objectors) or to the excessive diversification of the pupils caused by different programs of integration or compensation. Many school actors believe that this increase in the comprehensive period of instruction is only of benefit to, and actually was invented for, the most disadvantaged pupils, with no regard for those who are characterized as “above average.” These discourses make very clear the tension between comprehensiveness – the typical option of education policies in the welfare state – and efficiency, the preferential aim of neoliberal policies (Simola *et al.*, 2002).

The same constants apply to the relationship between the family and its relation with the school. The family naturally continues to be considered key as a socializing agent and, therefore, essential for the development of the new educational system. Yet its participation in school life – highly valued by the reform – has fallen short of expectations. If the family does not participate, the system begins to break down – this is one of the most repeated conclusions in the interviews analyzed, especially when the object of consideration is inclusion and exclusion. For many, the cause of exclusion resides not in the school but in the family, in society, and in the very individuals who suffer it. As registered in our “cognitive unconscious” (or the realm of thought that is completely and irrevocably inaccessible to direct conscious introspection: see Lakoff & Johnson, 1999), school, by itself, rarely excludes.

This rhetorical exoneration of the school is predictably present in narratives that give this institution a sort of “magic aura” inscribed in a “story of salvation” to which all individuals are summoned regardless of their origin or condition. However, as we all know, this is a strategy of deception, proved by the preeminence of nostalgia among many teachers or the hard-line defence of that ideal pupil, the highly competitive “cosmopolitan” student mentioned earlier.

But let us firstly admit that the effect of including the excluded is not necessarily inclusion. As Goodwin (1996) suggested, the frontiers or limits of marginalization are mobile and constantly shifting. The solution proposed by educational actors for these “readjustments” is an amalgam of ambiguous measures such as dialogue or education in values or other supposedly integrating and equally imprecise formulae meant to encourage the egalitarian dimension of education. What really happens, then, is that what is in fact a sociopolitical problem is denaturalized and turned into an individual question of moral or ethical conscience. The narrative effect of this transformation is a

host of weak, diffuse images (a “humanitarian soup” as the Spanish leading sociologist Manuel Castells would say) that do not reward reflection or lead to the invention of new creative formulae of governance that could be useful in overcoming the spaces of classification and normalization so firmly embedded in the school system.

In a more general view, we could say that social inclusion–exclusion in the educational sphere causes the emergence of different, socially distorted school cultures. The prevailing models (discourses and images) are those that opt for a school based on success and results, where there are no insurmountable barriers for individual effort and perseverance in study, as against the other models and traditions that put emphasis on social and economic factors (Silver, 1994). The question of equity is translated into a system of reason that labels, differentiates, and divides the subjectivity of educational actors and agents according to certain normalization procedures.

School educates, that is, it qualifies and capacitates students, but at the same time it normalizes them depending on their comprehension of, and proximity to, this new and all embracing, but likewise contradictory, legitimacy. This “new legitimacy” has been queried in various ways by educational actors, whose image of the school is distinct from that optimistically presented by the Socialist reform of the 1990s. Many of them felt tired and disappointed upon seeing how, behind all the modernizing rhetoric of efficiency and quality, there remains an insufficiently creative school guided by traditionalist models and values. The future is uncertain. Freedom and autonomy are a mirage and the level of student achievement continues to drop alarmingly (in particular in secondary education). Teachers are trapped by the demands of the educational authorities, the families, and society, but above all they feel they are undervalued and alone in the face of a task that is beyond them. The “ideal” student imagined and desired by the educational reform, society, and teachers bears little resemblance to the “real,” unmotivated, and even aggressive student who is actually present in the classroom (González Faraco, 2003). School has changed but its future is the murkiest image of all.

Such scepticism and uncertainty contrast with the extraordinary confidence shared by the vast majority of the educational community in the egalitarian condition of today’s school. The same is not true when deciding on the reasons for failure and exclusion. For the students, it is a fundamentally personal process, whereas for the other educational actors its origin is essentially social. The latter admit self-exclusion, but consider that exclusion is a socially produced artifact (Jamrozik & Nocella, 1998) and that only society is capable of setting it right, so that the initial confidence in the school’s integrating capacity now becomes doubtful. However, no one doubts that public and private schools (a decisive duality in the Spanish educational system) differ in their perception of social inclusion and exclusion and other closely linked concepts such as “equal opportunity,” “attention to diversity,” and “school autonomy.”

Taking these differences into account, the most widespread impression is still that the school cannot solve problems that society has not been able to solve heretofore, that it is not ready to accept all sorts of pupils, and that it has little to offer pupils with difficulties, who end up excluding themselves. Therefore, it merely confirms the marginalization of those that society has already marginalized. Consequently, for many educational actors progress toward cultural plurality, which should not be a plurality

of cultures but a plurality of culturally defined communities (Bauman, 2000, 86), is no more than a beautiful dream.

This confused panorama presents many interrogatives, but there is one above all, directly related to education and its relations with social inclusion and exclusion, that we find especially worrying: what is to become of the school system and those involved in it if it is not openly recognized that its capacity for exclusion, differentiation, and segregation remains intact, even though it is masked and hidden beneath flowery rhetoric?

Notes

1. In March 2004, the Socialist Party returned to power. One of the priorities of its program was to halt the application of the Law of Quality (LOCE) and reform it along the basic premises of the LOGSE. In April 2006, the Spanish Parliament approved the new Organic Law of Education (Ley Orgánica de la Educación, 2006). The Conservative Party voted against the new reform. One of the few important innovations introduced by the new law is referred to the development of schooling for children from 3 to 6 years old which is becoming free.
2. To this end, we used a large number of interviews based on the theoretical categories of the EGSIE, an international project of comparative research carried out between 1998 and 2002. *Education Governance and Social Integration and Exclusion in Europe* (EGSIE) was a Targeted Socio-Economic Research (TSER) project of the XII Directorate General Research of the European Commission coordinated by Sverker Lindblad and having Thomas S. Popkewitz as an international expert. We conducted 82 interviews, mostly from the regions of Andalusia and the Canary Islands, which may be characterized by their peripheral geographical location within the European Union and by their modest economic development by Spanish standards (see: Lindblad & Popkewitz, 1999, 2000, 2001; Popkewitz, Lindblad & Strandberg, 1999). (See also other publications arisen from this project: Pereyra, 2001; Johannesson et al., 2002; Lindblad et al., 2002; Lundhal, 2002; Rinne et al., 2003; Alves & Canário, 2002 and 2004). The Spanish version of the final report of the Spanish case appears in Luengo (2005, ch. 7 & 8).
3. The political discourse of school reform is dominated by the “millenarian” idea of the beginning of a new age (Popkewitz et al., 1986). In this sense, one teacher’s mention of “evangelism” in the 1990s Socialist reform is not accidental.

MODERNITY, STATE-FORMATION, NATION BUILDING, AND EDUCATION IN GREECE

Andreas M. Kazamias

In Europe, North America, Asia, and certain countries of the Middle East, e.g., Turkey, Lebanon, Israel, and Cyprus, institutionalized education in schools and universities and more broadly *paideia/culture*, have been considered to be important mechanisms in the formation of modern states and the building of nations since the period of the Enlightenment in the closing decades of the eighteenth century and the beginning of the nineteenth. From this perspective, education has been examined both as a factor contributing to nation/state-building and as a function of it (Green, 1990). By the role of education in the process of state-formation and nation-building in modern democratic polities one understands its (education's) role in cultivating social cohesion, citizenship, national culture, and national identity as well as in the education and training of personnel for the civil bureaucracy and the national and local state government apparatuses.

This chapter investigates the formation of the modern nation-state of Greece and the role of education, both in the narrow sense of schooling and in the broader sense of *paideia*, in this nation-building process. The case of Greece represents an empire-to-nation-state transformation, namely, the emergence and construction of a modern national state from the Ottoman Empire after a War of Independence in the 1820s. The afflatus for the political formation of the Greek nation-state and the concomitant formation of a national system of education was the Western European mixture of institutions and magma of significations known as the Enlightenment, which, inter alia, included constitutionalism, republicanism, democracy, the notion of the 'citizen' (*citoyen*), progress, rationalism, liberty/freedom, secularism, nationalism, the nation-state, the separation of Church and State, and a national public/state system of education (Harvey, 1990).

The method of approach of this study may be called 'comparative historical analysis.' Following an overview of the premodern traditional Ottoman Empire setting, the Greek nation-building historical trajectory will be examined, paying particular attention to the role of education in the modernization and concomitant nation-state building process. The key concepts in this historical analysis are empire, state, nation, modernity, modernization, westernization, Europeanization, secularism, education, democracy, education, and *paideia*.

The Premodern Ottoman Empire Setting: An Overview

In its pre-nineteenth century ideal-typical form the Ottoman Empire could be described as a multiethnic, multireligious, and polyglot sociopolitical formation, in which power and authority, centering in Constantinople (later Istanbul), were vested in, and emanated from, a dynastic, divinely sanctioned Sultan-Caliph, and wielded by him and his palace clique through a hierarchically organized administrative, military, and religious (Muslim) bureaucracy. The Sultan's authority and supervision over his multiple ethno-religious "subjects" (Muslims, Christians, and Jews) were carried out through the system of *millets* (religious 'nations'). The Orthodox Greeks, together with the other orthodox ethnic groups, scattered all over the Empire (the Serbs, the Romanians, the Bulgarians, the Vlachs, and the Orthodox Albanians and Arabs), constituted the *Millet-i Rum* (Greek Orthodox *millet*) which until well into the nineteenth century was the largest and most prominent. This institutional arrangement, according to an authority on the subject, "provided on the one hand, a degree of religious, cultural and ethnic continuity within these (the non-Muslim) communities, while on the other it permitted their incorporation into the Ottoman administrative, economic and political system" (Karpát, 1982: 141–142).

Ottoman society was differentiated, vertically and horizontally, along social, cultural, religious, and political lines. More specifically, it was divided into a privileged, politically and religiously Muslim-dominant Ottoman, and mainly Turkish ruling class, and a nondominant, religiously heterogeneous and politically disenfranchised "subject class," the *rayas*. Each of these classes had clearly defined legal rights, duties/obligations, and functions: the rulers—predominantly Moslems—were responsible for governing, exploiting, and defending the imperial wealth, and the subject class for providing the imperial wealth, as well as for catering to their own religious, social, cultural, and educational needs (Vryonis, 1976: 46, 54–55).

The subject class was, in turn, bifurcated into Muslims and Dimmis (non-Muslims) and into urban and rural dwellers (peasants), again with differentiated status and power attached to each category. The non-Muslim groups were separated from their Muslim counterpart and from each other culturally, politically, legally, and economically. Added to such divisions and bifurcations one must note the urban–rural dichotomies as well as the geographic dispersal of the members of each *millet*, which was especially the case with the Greek Orthodox *millet*.

As was the case with all the *millets*, many members of the Greek Orthodox *millet* lived in isolated rural and self-sustaining small villages. Another characteristic was that religion exerted an important influence in the society in general, and in education in particular. And, although those who were educated were accorded a favored position in the society, the majority of the Greeks, as well as the Turks and the other ethno-religious groups were illiterate or semi-educated. Lastly, the identity of all groups in the Ottoman Empire was quintessentially religious than "ethnic." The Greeks, during the period of the *Tourkokratia* (the Ottoman period from 1453 to 1821) were known as *Romioi*, an appellation that signified their Greek Orthodox "religious" rather than "ethnic" identity. It was not until the period of the Neo-Hellenic Enlightenment, in the latter half of the

eighteenth century and the opening decades of the nineteenth century, that the Greeks began to identify themselves as both Orthodox Christians and ethnic Greeks.

Compared to the other ethno-religious groups of the Ottoman Empire, and unlike the Ottoman ruling Turks, the urban Greeks cultivated their entrepreneurial and commercial interests. In some parts of the Empire, notably in Constantinople/Istanbul, the Greeks virtually controlled banking, commerce, and small business. Most importantly: while the Ottoman Turks, for religious, political, and historic reasons, considered European ideas, culture, and education alien and threatening, the more enlightened Greeks, with some qualifications, identified themselves with Western ideas and civilization, particularly during the post-European Enlightenment period. Numerous Greek communities existed in all the major European capitals and cities (e.g., Paris and Vienna), maintaining lines of communication with the Greeks of Anatolia, Constantinople and the Greek chersonese/peninsula. Contacts with the Western world on the part of the Greeks during the *Tourkokratia*, especially during the century or so preceding the War of Independence in the 1820s and the establishment of the modern Greek state in 1830, were further strengthened by the so-called *Phanariotes*, Greek Ottoman subjects who, because of their education and socioeconomic status, had attained high administrative positions—*dragomans* of the Porte, diplomatic emissaries in foreign countries, rulers of principalities under Ottoman suzerainty—in the Ottoman political hierarchy. Furthermore, the Christian character of Europe facilitated cultural links between the Europeans and the Greeks, which were reinforced by a common anti-Muslim Ottoman Turkish attitude. The Orthodox Russians, for example, in the guise of Orthodox Christian redeemers, constantly harassed the Sultans, aroused the coreligionist Greeks, and sprinkled the Empire with imperial agents.

Education in the Greek Orthodox *millet* was the responsibility of the Greek Orthodox Church headed by the Patriarch of Constantinople. Local communities or parishes in greater Constantinople and in most cities and towns of Anatolia and the Greek peninsula maintained “common” (*koina*) and/or “Hellenic” (*hellenika*) schools from church contributions and private donations. In the villages the local priest was also the teacher. Certain schools, attached to the Patriarchate in the Phanar section of Istanbul, notably the Great National School (*He Megali tou Genous Scholi*), were regarded as the training grounds of the intellectual and religious leaders as well as many of the schoolteachers of the Greek Orthodox *millet*.

The parish schools and the higher schools in Istanbul sought to develop in the Greek youth primarily a religious not an ethnic identity through catechism in the principles, dogmas, and precepts of the Greek Orthodox faith. With an important differentiating qualification: within the framework of the relative autonomy of the *millet* system of Ottoman government in education, what we have elsewhere called “controlled toleration” (Kazamias, 1991), Greek schools in certain areas also taught the Greek language, Greek philosophy, and Greek literature. Given this distinguishing factor, one could say that education in the schools of the Greek Orthodox *millet* opened up wide intellectual and cultural horizons for the Greek children (Kazamias, 1966; Kazamias, 1968).

The Advent/Challenge of Euro-Western Modernity and Nation- /State-Building

Social, political, and intellectual historians have maintained/argued that the European Enlightenment and the concomitant political and economic changes towards the latter decades of the eighteenth century and the ensuing decades of the nineteenth century ushered in the modern era and the associated modernization/modernity dynamic in Euro-American history. The Euro-Western Enlightenment ideas of freedom, national independence, and nation-state building had a strong and decisive influence on the Greeks of the Ottoman Empire much earlier than they did on the other Ottoman subjects. By 1830, the Greeks had attained independence and soon after established what the historian K. P. Kostis has appropriately called a “proto-modern state” (Kostis, 2006: 57). The Ottoman Sultans, on the other hand, introduced some western/modern techniques, institutions, and ideas into the Empire in the nineteenth century, mainly in order to consolidate the dissipating authority and efficiency of the government, and thus strengthen a reformed Islamic Empire-State. It was not until the opening decades of the twentieth century that efforts were made to restructure rather than reform the Empire, and not until 1923 and after, that a radical break, similar to that of the Greeks a hundred years earlier was made with the dismantling of the Ottoman Empire-State, after an internal “revolution,” and the establishment in its place of the modern Turkish Republic.

Euro-Western Modernity and the “Proto-Modern” Greek Nation-State

In the last three decades of the eighteenth and the first two decades of the nineteenth centuries, there was a noticeable intellectual and cultural “neo-Hellenic” national awakening among the Greeks stemming largely from Greek émigrés and from Greek mercantile *paroikies* or communities, mainly outside the boundaries of the Empire, in central Europe, the Balkans, southern Russia, and throughout the Mediterranean (Clogg, 1992: 23–25). Nurtured in the Euro-Western Enlightenment ideas of freedom and national independence, and French Jacobinism, Greek intellectuals and political activists (e.g., Adamantios Korais and Rhigas Velestinlis/Pheraios), through word and deed, exhorted the Greeks of the Ottoman Empire to recapture the spirit of their illustrious ancestors, to rise against the Ottoman rulers, and to “resurrect” the Greek “nation.” In the face of Ottoman decay and the weakening of the Sultan’s power over the provincial governors, in the Peloponnese and Epirus in particular, the Greek insurrectionists, with outside help, were able to overthrow Ottoman rule and thus opened the way for the establishment of an independent state (Kitromilides, 2000).

In the first decade of independence (1833–1843) the form of the newly established state or system of government was an absolute monarchy imposed by the European powers—England, France, and Russia. Absolute power was wielded by the imported Prince Otto of Bavaria, who was enthroned as king and who, in turn, was aided by a coterie of Bavarian “ministers” and officials (Svoronos, 1976: 77ff). “In form,” Keith

Legg, a student of comparative politics, has written, “the Greek kingdom was similar to a colonial administration ... all appointments and revenue remained the prerogative of the king; there was no constitution or representative assembly, and the participation of Greeks in the formal decision-making structures of the kingdom was negligible” (Legg, 1969: 55).

By 1864, the new Greek state developed into a western form of constitutional monarchy, “equipped with the trappings of liberal parliamentary democracy” (Clogg, 1992: 51). In 1862, King Otto was dethroned and a new Assembly (*Voule*) was elected, represented disproportionately by a rising wealthy bourgeoisie who were supported by the large landowners (Svoronos, 1976: 96). In 1863, another European prince—Prince George of the Danish House of the Glucksburgs—was enthroned as King George I of the Hellenes and in 1864, a new Constitution was promulgated (Clogg, 1992: 55–56).

The Greek state/polity, as constructed by the Constitution of 1864, has been characterized as Constitutional Monarchy, Crowned Democracy (Svoronos, 1976), and even as Parliamentary Democracy (Dertilis, 2005). The Constitution of 1864, continued to grant the King considerable power: he was declared “irresponsible”; he could appoint and dismiss his ministers and all officers and officials; and he could suspend or prorogue the *Voule* (Clogg, 1992: 51; Bickford-Smith, 1893: 263). Furthermore, while the press was declared “free” and “censorship” was prohibited, publications could be seized “in case of insult to the Christian religion, or to the person of the King.” And while all Greeks were declared “equal before the law,” only Greek citizens could be admitted into the public service (Kazamias, 1974: 20). At the same time, the Constitution of 1864 contained distinct democratic elements, viz., “all authority emanated from the Nation, certain royal privileges were limited, legislative authority was the responsibility of the popularly elected *Voule* and executive power belonged to the King, which he exercised through his responsible ministers” (Svoronos, 1976: 76).

In more recent historical studies (Dertilis, 2005; Kostis, 2006) the Greek political system that was established during the postindependence early period (1833–1864) has been characterized as a “proto-modern” liberal democratic state. According to Dertilis (2005: 764–765):

Greece is one of the first counties in the world that adopted the right of universal male suffrage, and established a form of democratic parliamentary regime, however incomplete, problematic, intermittently unstable and with varying degrees of democratization and authoritarianism it may be characterized ... [this system] was implanted into an entrenched older system of patronage which linked the patrons of the upper classes with the farmers/the agricultural population. This implantation created a special/unique and equalizing mixture of democracy and patronage/clientism.

In addition to such democratic deficits as “patronage” and “authoritarianism,” the appellation “proto-modern” rather than “modern” to characterize the newly formed Greek state, is appropriate because, as the historian Kostis quite rightly points out, the Greek polity was not entirely “secularist” in that there was no clear Church–State separation, as is commonly the case with “modern nation states” (Kostis, 2006: 51).

It should be noted here that by a royal decree in 1833, the Orthodox Church, hitherto under the Patriarchate of Constantinople, was proclaimed to be independent from the Patriarchate, and be known as the “autocephalous” national Church of Greece with its own independent Head and Holy Synod. By the same token, however, although Orthodoxy was recognized as the established religion of the new state and was granted “a privileged position in relation to other religious establishments,” by the royal decree of 1833 the Church recognized the King as its head, thus making it “subservient to the state” and essentially turning it “into a state agency under the supervision of a ministry, called the Ministry of Education and Religions” (Koliopoulos & Veremis, 2002/2004: 141–42).

The restrictions on the power of the Church over political, social, and cultural activity—including education— notwithstanding, religion as a body of doctrines and beliefs, and as an organized institution—the Church—continued to be an important element in the constitution and the functioning of the independent nation-state. Religion and the Church were particularly important in the field of education and the general cultural orientation of the people. Religious instruction and other religious exercises (e.g., church attendance on Sundays and holidays) were compulsory for all schoolchildren. In the formation of the “proto-modern” and later “modern” state, the Greek Orthodox Church did not relinquish its traditional function/role of articulating and guarding the ethos of the Greek nation or the ideals, values, and aspirations of the common Greek. It was the Bishop of Patras that signaled the uprising in the Morea in 1821; and priests had fought in the War of Independence literally with guns and figuratively with icons and prayers. The ideology of an expanded Greek State—the *Megali Idea* (Grand Idea)—which pervaded Greek national life down to the first decades of the twentieth century, was in part fanned by many clergymen who continued to look toward Russian help to reestablish the older Christian Byzantine Empire. In short, to the Church, faith (*pistis*), nationalism (*ethnikismos*), Hellenism (*ellinismos*), and education (*paideia*) were inextricably intertwined (Kokosalakis, 2004: 26–39).

Education and the Proto-Modern Hellenocentric Nation-State

Education/schooling, the historian Hobsbaum has written, in the nineteenth century “was the most powerful weapon ... for forming nations” (quoted by Green, 1990: 35). The importance of education in the building of the Greek nation-state was emphasized by the Greek intellectuals mentioned above, who lived in Europe in the years prior to the outbreak of the War of Independence in 1821 and who were nurtured in the European Enlightenment ideas of individual liberty, constitutionalism, republicanism liberalism, equality before the law, the nation-state, popular sovereignty, citizenship, and national consciousness. (Petropoulos, 1968:140). A leading figure in the Neo-Hellenic Enlightenment, as noted above, was Adamantios Korais (1748–1833). A classical scholar living in Paris, Korais, according to John Campbell and Philip Sherrard, two Oxford scholars, “envisaged the “emancipation” of Greece in

terms of the secular liberalism and humanist enlightenment of the contemporary West” (Campbell & Sherrard, 1968: 41). Koraes believed that to attain true freedom, the largely uneducated Greek Christian Orthodox Ottoman subjects—the *rayas*—must be enlightened and educated by being imbued with the ideas and values of western liberalism and classical Greek *paideia* (culture) and by developing “a formal [Greek] language for scholars and the state” (Koliopoulos & Veremis, 2002: 8). And, in line with the political ideology of the Enlightenment, Count John Kapodistrias, who in 1828 was elected as the first “Governor” or President of Greece by the revolutionary Assembly of Troezen, also placed high value on education as an instrument of political development, state-formation, and nation-building. “The spread of education and the acquisition of freedom,” according to his biographer, “constitute for Kapodistrias two coextensive meanings (Koukou, 1958: 32). Kapodistrias was also impressed by the modern pedagogical ideas of Pestalozzi, as developed by de Fellenberg in Switzerland, which he introduced into the Ionian Islands and later into free Greece. At the same time, Kapodistrias believed that good education must be based on the ethical principles and spiritual values of the Christian religion (Kazamias, 1974: II-5).

Kapodistrias’ aim insofar as education was concerned, was to establish elementary schools in every village and province; as to more advanced instruction, his avowed policy was “to institute central schools in the different provinces of the nation” (Kaldis, 1959: 173). But, following Kapodistrias’ assassination, the construction of a “national system of education” as a basic desideratum of state-formation and Greek nation-building was left to King Otto and his Bavarian bureaucracy. This was done in the 1830s with the enactment of three decrees which laid down the statutory basis for the construction of such a system: one decree in 1834 on the organization of elementary education; another in 1836, regulating secondary education; and a third in 1837, establishing a university. Briefly, the so-called Bavarian Plan for a national system of education provided for a centralized, graded, and selective system of education consisting of compulsory elementary schooling for all children between the ages of 5 to 12, first level secondary education in middle schools known as Hellenic schools (grades 5–7), selective upper secondary schools known as Gymnasia (grades 8–11), and a selective university called the Othonian University. As with the new state, the newly constructed system of education was centralized, authoritarian, and bureaucratized. The respective decrees/laws specified in detail the curriculum of the elementary schools, the Hellenic schools, and the Gymnasia, as well as the qualifications, the classification, and the salaries of teachers. Authority and responsibility for all educational matters (appointment, transfer, and dismissal of teachers, curricula/programs of study, supervision of schools) were vested in the central organs of government (Dimaras, 1973; Bouzakis, 1999/2002).

In its institutional structure and governance, the educational system of the “proto-modern” Greek state, as established in the postrevolutionary years, reflected post-Enlightenment continental European modernist patterns, viz., centralization and bureaucratization; compulsory public and essentially secular elementary/popular education; selective secondary and university education; curricula/programs of study that emphasized the nonpractical, nonscientific “humanistic canon” (the classics and

languages). In structure and ideology, the elementary education law of 1834 bore a strong resemblance to the French Guizot Law of 1833; the Hellenic school and the *Gymnasion* were virtual replicas of the German *Lateinische Schule* and *Gymnasium*; and in its mission, organization, faculties, and programs of study, the Othonian University (named after King Otto) reflected the nineteenth century German neo-humanist “idea of the university” associated with Wilhelm von Humboldt (Bouzakis, 1999/2002: 40–45; Phirippis, 2007).

From the above, it can be seen that several features of the newly constructed Greek national system of education were “transferred” to the fledgling proto-modern Greek state from post-Enlightenment Europe, mainly from France and Germany. Such an educational transfer has been criticized by Greek leftist historians as involving the uncritical transplantation and imposition of a Western, centralized, elitist, and classicist educational system that was foreign to the Greeks of the Ottoman Empire and had no relation to the Greek contemporary realities (Bouzakis, 2002; Katsikas & Therianos, 2004). Such an interpretation, however, oversimplifies a complex historical phenomenon and is at best misleading. For one thing, the contemporary Greek intellectuals and commercial elites, as indicated above, were themselves favorably disposed to the introduction of Western European educational ideas and institutional patterns, e.g., centralized state education and classical humanistic curricula, from what they considered to be an Enlightened Europe (see Dimaras, 1973). Another factor that must be considered is that “classicism” did not only occupy a central position in the curriculum of the European secondary schools—the *lycees* in France, the *Gymnasien* in Germany, and the Grammar and Public School in England—and the European universities (Butts, 1947: 429–435); it was also not alien to the schools of the Greek Orthodox *millet* of the Ottoman Empire. Furthermore, classical Greek education was very prestigious in post-Enlightenment Europe and America (Winterer, 2002). And when the Greek War of Independence broke out, Europe was swept by Philhellenism and classical humanism. In the case of the German neo-humanism and the so-called *Hellenomania* of the nineteenth century as advocated by, among others, Wilhelm von Humboldt, Friedrich Wolf, Gottfried Fichte, Friedrich von Schiller, and Friedrich Schleiermacher, it was believed that the study of the ancients and Greek antiquity (*Altertumswissenschaft*) would regenerate morally and politically the German people after the defeats they had by Napoleon, it would unify them and create a modern German nation (Bernal, 1987: 283–295). Considering these endogenous and exogenous circumstances, it would not be unreasonable to postulate that in the Greek case, the transferred educational cultural forms, notably Classicism, were quite understandable. Indeed, “classical education” in the minds of the Greek intellectuals, especially the influential classical scholar Koraes, was necessary for the liberation and “resurrection” of the Hellenic/Greek nation and culture which were traced to ancient Hellas and medieval Byzantium, and whose continuity was interrupted by the Ottoman conquerors. Modernity in the new state, therefore, meant to a large degree the revival of older/ancient Hellenic and Byzantine Christian values, attitudes, and states of mind. Stated in another way, modernity in the Greek state meant the creation of a modern Greek national identity by reinventing the classical Hellenic and the Byzantine Christian traditions (Koliopoulos & Veremis, 2002: 242–243).

Education, the Greek State, and Nation-Building: Transforming the Rayas—the Ottoman Greek Subjects—into Hellenes/Citizens of Hellas

“The nation is not the cause but the result, of the State,” the savant Lord Acton has once said, and further “it is the State which creates the nation, not the nation the State” (Quoted by Emerson, 1962: 114). The mechanisms for forging national identity and building the modern Greek nation-state included: (a) a centralized national educational system—elementary, middle, and secondary schools, and postsecondary higher institutions; (b) a “constructed” common national language; and (c) a “constructed” historical cultural tradition. Modernity and nation-building in the new state meant to a large degree the revival of ancient Hellenic ideas and values, hence in the schools there was a strong emphasis on classical Greek *paideia* coupled with the reinvention of the Byzantine Christian tradition (Koliopoulos & Veremis, 2002: 242–243). The cultivation and promotion of Greek national identity, of being “Greek” and Orthodox Christian, was carried out through the manifest curriculum—especially through the emphasis placed on the classical Greek language and culture and the teaching of the Greek Orthodox religion—and through the “hidden” curriculum, e.g., the celebration of national holidays, compulsory churchgoing, and though other Helleno-Christian rituals (Dimaras, 1973; Katsikas & Therianos, 2004). Additionally, the Othonian University, later in the century renamed National and Kapodistrian University of Athens, was conceived to be a national institution and an important mechanism in Greek state-formation and nation-building. Its mission, among other things, was (a) to construct and cultivate a Hellenic ethno-cultural identity through the cultivation of classical Greek *paideia*, and (b) to educate and train echelons for the civil bureaucracy in the national and local state apparatuses (Phirippis, 2007).

Building the Modern Liberal Democratic State—1909/1910–1935—A Paternalist Democratic State?

The 60-year period, following the enactment of the new constitution in 1864, was a period of irredentist Hellenocentric nationalism, territorial expansion, internal upheavals, intermittent wars, the rise of a “bourgeois middle class,” political liberalism, and the adumbration of an interventionist Welfare State. It was also a period of neo-Hellenic cultural revival, of educational reform and “non-reform.” A hegemonic element in the Greek nation-building ideology until 1923 was the so-called Great Idea (*Megali Idea*), the irredentist ideology and policy of creating a greater Helleno-Christian state with the reinstatement of Constantinople, the fallen Byzantine metropolis, as its capital. Modernization and nation-building during this period signified an invented nationalist tradition that combined classical Hellas, Orthodox Byzantium, and Enlightened Europe, and the development of a national system of education with the same constituent elements. Notable among the state-formation developments during this period was the Revolution of Goudi in 1909 by the Military League and the emergence of the

Liberal Party under Eleftherios Venizelos, a rising political star from Crete, representing the rise of the bourgeois middle class as a modernizing liberal political force.

The 1909 Revolution of Goudi marked the end of an era in state-formation and nation-building and the beginning of another, namely, the construction of a modern liberal democratic state. Venizelos and the Liberals, who were voted to power in 1910, envisioned the construction of a modern right-of-center liberal democratic state modeled after the contemporary Western European prototypes. The revision of the Constitution in 1911 was a step in that direction. According to the revised Constitution, individual liberties were guaranteed and the foundations were laid for a Welfare State. Within this constitutional framework, and in line with developments in contemporary Western Europe, the Venizelos liberal state was to be an “interventionist, rather than a *laissez-faire* liberal state” (Tsoucalas, 1981; Tassopoulos, 2006). By 1920, as Eric Hobsbawm has written, Greece was among the many states of Europe west of the Soviet borders that had liberal constitutional governments (Hobsbawm, 1995: 146–147).

Essential tools in the building of the Greek liberal state and concomitantly, in the development of national identity were education, language, and history. During the period of 1863/4–1923 developments in national education were uneven, marked by actions and reactions and the interplay of traditional conservatism and liberal modernity (Dimaras, 2006). In 1899, 1913, and 1917, state-initiated efforts were made to modernize the structure and orientation of the educational system and the school curriculum by bringing it more in line with developments in Western Europe, and adjusting it to the developing capitalist economy and a bourgeois class society (Bouzakis, 2006). Actually, most of the recommended reforms were not enacted and remained on paper only.

Nevertheless, some aspects of the state-initiated reform movement as well as some non-state-initiated modernizing cultural and educational developments during this period are noteworthy. First and foremost, was the state-initiated “language educational reform” (*glosso-ekpaideutiki metarrythmisi*) that centered in the use of the *demotiki*—the spoken form of the Greek language—in the schools. In this connection, it should be noted that since the establishment of the national system of education in the 1830s, the language taught in the schools and the official language of the state was the *katharevousa*, a pure form of modern Greek that was different from the spoken “demotic” form, which also was the language used by the new generation of Greek literati.

The language reform effort and some other notable contemporary non-state educational initiatives such as the establishment in 1908 of the Girls’ Higher Elementary School of Volos by A. Delmouzos, a progressive *demotacist*, and the organization of the *Ekpaideutikos Omilos* (Educational Association) by contemporary leading educational *demotacists* in Athens in 1910, were integral parts of the neo-Hellenic sociocultural movement known as *demoticism* or *demotikismos*. *Demoticism* was a social and cultural modernization movement, in that it extended beyond the confines of pedagogy and the use of the spoken Greek language, i.e., the *demotiki*, in the schools. As such, it was envisaged as the medium for social integration and nation-building. According to Psycharis, a leading personality of the neo-Hellenic cultural revival and *demoticism*:

Two things are required for a nation to become a nation: extension of its territorial boundaries, and the creation of its own literature. When it demonstrates that it

knows what the value of the popular language is and when it is not ashamed of this linguistic form, then we shall see that it has become a nation. (Kordatos, 1943)

Related to language and Greek nation-building was history. After the formation of the Greek state, it was necessary to transform the Greek *rayas*, known as *grae-koi* or *romaioi/romioi* (Romans) into *Hellines polites* (Hellenic/Greek citizens), an appellation that signified the formation of modern ethno-national Greek citizens by returning to the *Hellenes* (Greeks) of classical Hellas (Greece). In this process, history as constructed by the nationalist historian Constantine Paparrigopoulos argued that there was an unbroken continuum in the history of the Greek nation or *ethnos* that was divided into three phases—the Classical Hellenic, the Byzantine Christian, and the Modern European. In this manner, as Gallant notes, Paparrigopoulos “created a unity out of the Greek past and, of equal importance, a unity of all the Greek people” (Gallant, 2001: 72–73. Also see Koliopoulos & Veremis, 2004: 231–235; Clogg, 1992: 2–3).

Other educational mechanisms used to “Hellenise” a regenerated Hellenic national state, in addition to language and history, were geography, architecture, literature, folklore, and archaeology. According to Gallant:

Thus through architecture, education, art and literature, in public festivals and celebrations, came to internalize the new national Hellenic identity that incorporated both the Hellenic and Romeic, both the heritage of the classical world and the Orthodox Christian one. So successful was the process that, as Just, Herzfeld, and others have noted, all sense of it being an “invention” was lost. Instead an identity grounded in “history” became timeless and primordial. As a popular expression has it, “we have always been Greeks.” (Gallant, 2001: 74; Koliopoulos & Veremis, 2004: 243)

Venizelos’ liberal project, that included educational reform, what Tassopoulos has called “inclusive (liberal) constitutionalism” (Tassopoulos, 2006: 252), which was charted during the period 1911–1916, was not to be. Wars—the Balkan wars, World War I, and the disastrous Asia Minor campaign; coups and countercoups; and political crises, most significantly the constitutional crisis known as *Ethnikos Dihasmos* or National Schism, eroded the foundations of the Venizelist modernizing liberal constitutionalism. After an unstable interregnum, Venizelos and the Liberals, who returned to power in 1928, renewed their efforts to modernize the Greek state and strengthen the republican regime during Venizelos’ premiership in 1928–1932. Among these modernizing endeavors were certain institutional changes in the system of democratic governance, e.g., the establishment of the senate and the council of state (as the supreme administrative court), and reform in education and in the Welfare State by enacting a comprehensive scheme of social insurance. According to I. D. Stefanidis:

Social insurance was understood as part and parcel of a fairly paternalist conception of the modern state. The latter ought to care for the welfare and “peace of

mind” of the working class and provide mechanisms that could serve as “a safety valve against violent overthrow and revolution.” Although it did not come into full effect until 1937, law 5377 was a stepping stone to the Greek “welfare state.” (Stefanidis, 2006: 200–201)

In the new elections of 1933, under the plurality electoral system, the anti-Venizelist conservative political forces won a majority and they attained power. But political turmoil continued: two attempted coups, the short-lived Kondylis dictatorship, the restoration of the monarchy, and on August 4, 1936, the Metaxas fascist dictatorship. In the same year, Venizelos died in exile. Summing up the fortunes of the Venizelist liberal project, the historian Tassopoulos wrote:

Under these circumstances, Eleftherios Venizelos’ original project for an inclusive political system, bolstered with the safeguards and guarantees of the rule of law was abandoned and the institutional achievements of his first term in office were reversed and annulled. As a consequence, Greece’s constitutional institutions entered a long period of instability and crisis, which ended only in 1975. (Tassopoulos, 2006: 265)

The erosion of the Venizelist inclusive [liberal] constitutional project notwithstanding, one should not underestimate the historical significance of the already mentioned non-state modernizing educational initiatives, even though they were not entirely successful, or the equally unsuccessful state initiatives during the first Venizelist administration in 1913 and 1917 and the second in 1929. In both “episodes,” an attempt was made to reform and reorient the educational system by making changes in its organizational structure and in the content/curriculum and the pedagogy of schooling (Bouzakis, 2006: 75–78, 96–99). In the second episode (in 1929), Venizelos, the prime minister, declared himself in favor of restricting classical education to the “selected few” and strengthening vocational education, while George Papandreou, under whose Premiership later, in the 1960s, the famous liberal reforms of 1964–1965 were enacted, unequivocally declared that “since education belongs to the State ... the ideals of education are also the ideals of the State ... the ideals of our national education are the ideals of Greek democracy” (Quoted in Kazamias, 1974: 61 also see Kitromilides, 2006).

The Post-World War II Liberal Democratic State: The Political Dominance of the Conservative Right, 1952–1963

Following World War II and the Civil War of the late 1940s, there were significant changes in the Greek political landscape. From the perspective of this chapter, such changes can be interpreted as indicative of Greece’s continued process of developing and consolidating a stable Western European form of liberal democratic polity, or to put it differently, of “democratizing democracy.” One such change was the reconstitution of the multiparty system in the 1950s and 1960s. In addition to a strong ethnocentric and reactionary Right that attained and held power until 1963, there was

a resurgence of the Liberal Center, which, although fragmented, under the leadership of the veteran liberal George Papandreou managed to assume the reins of a short-lived government in 1963. Equally significant was the countable rise of the political Left. With the dismantling of the military dictatorship of 1967–1974, and the restoration of democratic rule in 1974, these reconstituted political forces—Conservative Right, Liberal Center, and Left (Socialist and Communist)—vied for political power in the restored and transformed democratic polity. In the elections that were held in 1974, a reformed rightist Conservative Party—the New Democracy—under K. Karamanlis, won the elections and formed a government. But seven years later, in 1981, the newly formed Panhellenic Socialist Movement (PASOK), under Andreas Papandreou, won the elections and formed Greece’s first socialist government. In the ensuing years, the two major parties—PASOK and the New Democrach—succeeded each other in the control of the state government. Today, the neoconservative right-of-center New Democracy is in power, with the left-of-center PASOK and the Communist Party of Greece (Kommounistikó Kómma Elládas, KKE) as the major opposition parties. The Liberal Center as an organized political force all but disappeared, but the contemporary Greek state can legitimately be characterized as a stable Liberal Democratic State.

In the meantime, there was a concurrent change in the Greek polity (*politeuma*), i.e., the constitutional structure of the state. In 1952, a new Constitution was ratified, which reaffirmed the previous principle/provision that the Greek polity was “crowned democracy” or a “constitutional monarchy” with the King retaining the same extensive powers as before. But with the restoration of democracy in the 1970s, the new Constitution of 1975 provided that the form of the Greek polity/state was changed to a Presidential Constitutional Republic/Democracy with all the rights—individual and social—and responsibilities of modern liberal democracies and democratic citizenship. The revised Constitution of 2001, in force today basically reaffirmed the principles and provisions of the 1975 Constitution. The contemporary Greek polity has been characterized as a modern liberal democracy, that is congruent with European and international developments, but with no qualification, namely, the relationship between the Church and the State.

As noted at the beginning of this chapter, the constructed postindependence “proto-modern” Greek state was not, strictly speaking, “secular” in that there was no clear separation between the state and the Orthodox Church. Orthodoxy was recognized as the established religion of the new state and was granted a privileged position in relation to other religious establishments. It was further noted that, despite restrictions on the power of the Church, religion continued to be an important factor in Greek nation-building. This rather ambiguous Church–State relationship and the role of religion in nation-state formation were reiterated in subsequent constitutions, including the one in force today. Article 3 of the 2001 Constitution states that the “dominant/established religion of Greece is the religion of the Eastern Orthodox Church of Christ.” At the same time, Article 13 provides of “freedom of religious conscience” which is protected by law. Related to this issue, however, is Article 16 which refers to education/*paideia*, and which states that “*paideia* constitutes a basic mission of the State and aims at the ethical, intellectual, spiritual, vocational and physical *agoge* (education/training) of

the Greeks, the development of ethnic-national and religious consciousness and the formation of free and responsible citizens” (<http://www.parliament.gr/politeuma.asp>).

As in the previous periods examined above, an integral part of the postwar modernization/westernization process of state-formation and nation-building, was the reform of the national system of education. The reconstruction and reorientation of the educational system were deemed all the more necessary in view of Greece’s initial association in the 1960s with the newly created European Economic Community, and after 1975, Greece’s quest to become a full member of the supranational European Union, under the famous motto “We Belong to Europe,” a goal which was accomplished in 1981.

The movement for comprehensive educational reform began in earnest in the 1950s and continued in the ensuing decades. Important reform “episodes” in this trajectory were those of 1964 by the Center Union liberal government of George Papandreou, of 1976–1977 by the New Democracy neoconservative government of Constantine Karamanlis, of 1982–1985 by the PASOK socialist government of Andreas Papandreou and of 1997–1998 by the PASOK “social democratic” government of Costas Simitis. In all these “episodes” the reform discourse revolved around the politico-social and sociocultural principles of “modernization” and “democratization”.

With socialist PASOK’S ascension/accession to power in 1981, the educational reform discourse began to take a more radical ideological trajectory. The educational discourse on PASOK’S political slogan of “change” (*allagi*) was framed mainly around the “policy talk” and “policy practice” of democratization, egalitarianism, “deconcentration and decentralization” in the administration/governance of the state system, “democratic planning in education,” public participation and self-government at the provincial and local levels, restructuring of universities (abolition of the authoritarian system of “chair,” and greater student participation in the decision-making organs of university governance), strengthening and upgrading of technical and vocational education, and restructuring of elementary and secondary education that included, inter alia, the establishment, on an experimental basis, of “comprehensive multilateral” lyceums (EPLs) (Kazamias & Kassotakis, 1995; Ministry of National Education and Religions, 1985; Kazamias & Roussakis, 2003).

PASOK’S educational reform orientation was consonant with the broader socialist reform ideology, called the “third way,” which aimed at a broader politico-socio-economic transformation. It is patently clear that the reform discourses during the first PASOK administration (1981–1985) had socialist leftist overtones and ideas drawn from contemporary ideologies that derived from a revived neo-Marxist tradition. But as A. Papandreou, the prime minister, declared, the vision was “a third-way socialism,” a participatory and democratic socialism, based on popular sovereignty (Papandreou, 1982).

The reforms of the PASOK governments of the 1980s did not measure up to the reformers’ high expectations in paving the way for the declared “third-way” socialist transformation of the modern Greek state and society. After 1985, the “third-way” socialist ideology was all but abandoned. By then, PASOK, still in power, had shifted its negative position regarding Greece’s European orientation (in 1981 Greece became a full member of the European Economic Community, later the European Union), and

had become unequivocally pro-European. Concurrently, its orientation veered towards the developing “neo-European” modernization trajectory, a path more towards a modern “social-liberal democracy” than the earlier “third-way” socialist democracy. This orientation became more evident after PASOK’s return to power in 1993, and especially after the death of A. Papandreou and the election of Costas Simitis as prime minister in 1996.

The PASOK new social-liberal democratic government embarked upon another ambitious program of educational reform that encompassed virtually all aspects of the educational system: governance, control, institutional organization, curricula, pedagogy, teachers, intercultural education, and the education of minorities. The reform discourse—policy talk and policy practice—of the Simitis government continued to revolve around the twin politico-socio-economic concepts/ideologies of “democratization” and “modernization,” with perhaps more emphasis on the latter, hence the characterization of Simitis and the PASOK reformers, e.g., G. Arsenis, the minister of education, as “modernizers.” The Greek educational “crisis” was perceived to be one of the persistence of chronic system pathologies and the “asynchronization” of the educational system with the European Union and the global *cosmos* that was being constructed and in which Greece chose to place itself. The persistent pathologies of Greek education included: (a) a centralized, bureaucratic, hierarchical, and cumbersome system of governance; (b) a double undemocratic educational network (general and vocational) that functioned differentially for social groups and “asynchronously” in relation to society and the world of work; (c) a type of schooling that was characterized by formalism, authoritarian pedagogy, and anachronistic educational knowledge; (d) high dropout rates; (e) inequalities of opportunity between urban and rural areas and among different occupational groups; and (f) social exclusion of ethnic and religious minorities.

The reforms needed to get out of the educational crisis, to correct the deficiencies of the system, and to modernize and democratize it, were spelled out in the government policy document *Education 2000—Toward a paideia of open horizons* (1997). A noticeable new note in the modernizers’ reformist discourse was that education must be functionally related to the economic and social developments in the international world, especially the European Union modernity *cosmos*. At the same time, the reform discourse emphasized such democratic principles and policy goals as: democratic education; participation of school principals, regional administrative officers, and school counselors in the evaluation of schools; teacher participation in the evaluation of students; a degree of decentralization in the planning of education (from the center to the regions); the institutionalization of a “unified lyceum” (*eniaio lykeio*), a “comprehensive” type of upper secondary school; abolition of the *numerous clauses* for a more open access to tertiary institutions; the modernization of the curricula and the “redefinition” of Greek *paideia* by making it less ethnocentric and more Eurocentric; and special programs for religious and ethno-cultural minorities and for children with learning disabilities (Ministry of National Education and Religions, 1997).

In connection with this chapter, it would be relevant here to refer to another reform discourse in the context of the recent Greek modernization and democratization trajectory. This is Law 2413/1996 that referred to intercultural education. It was the

first time that the modern Greek state officially recognized that Greek society was culturally diverse. The recognition of this phenomenon, which was in line with the contemporary European modernization discourse, has raised questions about the traditional ethnocentric character of the Greek educational system. The public discourses in this area have been of two kinds. The first has been called the “democratic humanitarian discourse,” which adopted a philanthropic and egalitarian point of view; it emphasized equal opportunity, nondiscrimination, and general welfare. The second type of discourse has been labeled “the discourse of xenophobia.” In this connection, it should be noted that “ethnocentricity” and the reproduction of national identity traditionally have been characteristic of Greek education. Nowadays, according to E. Zambeta, although these aspects of education are being criticized, many of the education political actors often lapse into ethnocentrism (Zambeta, 2001).

A Stronger “Guardian” or “Headquarter” State

The recent “modernization” and “democratization” reform discourse as presented above, could be interpreted to mean that the intention of the policymakers was to restructure the state steering and control mechanisms in Greek education in the direction of “decentralization” or “deconcentration” in decision-making and the governance of the system. However, on closer examination of all pertinent provisions in the relevant reform texts, a different picture emerges: that of a “stronger” and more “controlling” state. Contrary to the professed principle of the modernization cum democratization of the post-1974 Greek polity, what actually has emerged has been a “stronger” and more regulatory state. Indeed, in “modernizing” the state and its mechanisms of governance that included education, Costas Simitis when prime minister, and his political-ideological confreres in the government used the terms “strategic” and “headquarter state” (Kazamias & Roussakis, 2003: 22).

THE DEVELOPMENTAL STATE, SOCIAL CHANGE, AND EDUCATION

Wing-Wah Law

Since the modern state's emergence in the sixteenth century, theorists have articulated various approaches to understanding the development of different countries, the relative importance of the role of the state and markets in development, and the models and strategies of development that countries should follow. Of these approaches, the developmental-state thesis (and world systems theory) has been more useful in explaining the state's important role in economic growth and industrialization, particularly in East Asia and Latin America after World War II. Developmental states refer to countries that, compared to Western industrial countries, achieved "late development" (White & Wade, 1988b: 1). They include capitalist countries, such as Germany, Japan, Russia, South Korea, and Taiwan, and socialist countries, such as China, the former Soviet Union, and North Korea. Despite the severe challenges posed by the financial globalization crisis that took place in Asia in 1997, this statist approach is still useful in explaining the intertwined interactions of the state and markets for development and competition within and between national borders.

This chapter first introduces major theoretical frameworks for understanding development, the state, and markets. They include the theories of modernization, dependency, the world system, and the developmental state. The discussion focuses on the latter and the role of education in skills formation in developmental states. Second, the chapter examines challenges to the developmental-state thesis, both theoretically, in the literature of globalization, and practically, as exemplified by the 1997 economic crisis in Asia. Third, the chapter uses the cases of Japan as a capitalist developmental state and China as a socialist counterpart to illustrate the continuing significance of the state, markets, and education in nation-building and rebuilding and how states have used the economic and sociopolitical tasks of education for the cause of development. Finally, the chapter discusses the complex relationship between globalization and nationalism in development.

Major Theoretical Frameworks for Development, States, and Markets

Issues related to development, states, and markets have arisen at different times in the literature of development, particularly in the disciplines of development

economics and international political relations. Major development approaches include modernization theory in the 1940s and 1950s; dependency theory, world systems theory, and the developmental-state thesis from the 1960s to the 1980s; and the discourse about the globalization of world economies in the 1990s.

Theories of Modernization, Dependency, and the World System

Modernization theory and dependency theory both assume that the world is dichotomized, respectively, into modern and traditional sectors in the processes of differentiating social institutions and economic growth (Parsons, 1951; Rostow, 1985), and core and peripheral parts that engage in unequal economic exchange (Frank, 1971). According to both schools, industrialized countries in the West represent modern and core parts of the world, and the Third World countries represent traditional and peripheral ones. However, both schools have been criticized for their dualistic notions of the world, predicting in different ways a deterministically unilinear and pessimistic picture of economic development in Third World countries, undermining the state's role in their developments, and undervaluing their cultures (Martinussen, 1997; Worsley, 1985). These two schools also fail to explain the growth paths of a minority of latecomers in Latin America and Asia between the 1960s and 1980s, which differed from those of advanced developed countries in the West (Haggard, 1990).

The economic performance of these latecomers can be better explained by world systems theory and the developmental-state thesis. In contrast with dependency theorists, world systems theorists argue that the reliance on core countries by noncore ones does not necessarily lead to their economic underdevelopment. According to Wallerstein (1974, 1979), the world system consists of the capitalist world economy and the interstate system. The single, capitalist world economy comprises three tiers: core, semiperiphery, and periphery. All countries engage in the capitalist relation of unequal exchange in an endless pursuit of capital and labor. The "political superstructure of the capitalist world-economy," as further suggested by Wallerstein and Phillips (1991: 141), is the interstate system. Member states possess different capacities to intervene in the operation of the world market and can adjust their economic strategies to regulate the inflow and outflow of capital. They therefore may be able to change their status, for instance, from periphery to semiperiphery, or from semiperiphery to core, if they can achieve "development," or if they end up in "regression" (Wallerstein, 1975). However, Wallerstein's (1974, 1979) world systems theory has been criticized for advocating an over-deterministic domination of the world by capitalism and for undermining the qualitative differences between capitalist and the former socialist countries; paying too much attention to the system level while lacking specificity in understanding social relationships and institutions; and overemphasizing the ruling class's capacity to manipulate the system, but undermining the contribution of the ruled and social agencies to development through various efforts, including resistance to domination (Worsley, 1985).

The Developmental-State Thesis: The State's Role in Markets, Development, and Education

In a different way, the developmental-state thesis has provided an alternative line of thinking by bringing the state back in. Unlike dependency theory, which is based mainly on selected cases in Latin America, the development-state thesis was derived mainly from investigations on the rapid industrialization of capitalist economies in East Asia, including Japan, which was seen as a rising global economic power in the 1960s, and the four Asian Dragons (Hong Kong, Singapore, South Korea, and Taiwan) in the 1970s and 1980s (Amsden, 1989; Castells, 1992; Johnson, 1982; Wu, 1994). Unlike dependency theory, which holds a pessimistic view of development, researchers often use this statist approach to explain the economic growth of the second generation of Asia's newly industrialized economies, such as China, Malaysia, and Thailand, that emerged in the 1980s. Compared with world systems theory, the developmental-state thesis pays more attention to the state's relationships with the market and domestic institutions, and how they work together in the process of nation formation.

Developmental-state theorists also differ from neoliberal scholars in how they explain these late or late-latecomers. Neoliberal scholars and the World Bank attributed the late development of East Asian economies to the emergence of free markets within their territories and regions, and the economic failure of Latin American countries to excessive intervention (Kay, 2002). However, proponents of the developmental-state thesis challenged neoliberal beliefs in minimalist state and free-market-driven development and argued for the state's critical role, and its economic and social functions in development and economic progress. With reference to Japan, Johnson (1982) developed an institutionalist approach to understanding the developmental state. He argued that economic development can be successful without a totally free market when it is supported by guidance from the state and favorable political conditions (see more discussion about Japan later). Leftwich (2000) went even further by arguing for the primacy of politics over economics. In a milder version, Wade (1990) proposed a "guided market" approach and argued that in the case of Taiwan, the state's intervention in the market is not unimportant and both state's policies and market's dynamics can contribute to economic growth.

In such developmental economies, the respective states established development as the top priority in their long-term national interests; created a favorable environment with low economic risk and low cost to attract investors at home or from abroad; intensively intervened in market and development processes by controlling the composition of what is profitable, guiding and taming domestic and international market forces, and harnessing them for national economic interests; and cultivated a collective consciousness and urgency for development in policymaking and social mobilization (such as the use of external threats by the nation's foes) to achieve this development task (Evans, 1987; Gereffi, 1990; Johnson, 1982; White & Wade, 1988a). The developmental economies in East Asia, as Castells (1992) noted, have five commonalities: the existence of emergent situations that demand urgency for development and survival, the adoption of an outward economic orientation, the lack of a rural landowning class, an ability to govern the labor force and re-skill it for development, and high ability

and flexibility to adapt to rapid changes in the global economy. Many factors can account for differences in developmental states' economic performances: differences in the state's capacity and relations with the economy; the state's choice of appropriate development strategies; domestic preconditions, such as national histories, cultures, and social class structure; and international factors, like international relations (Evans, 1987; Gereffi, 1990; Kay, 2002; Vartiainen, 1999).

In addition to these factors, numerous theorists have cited education and training as an important engine for economic growth during postwar period, particularly in East Asian developmental states. In developmental states, the state is a principal shaper of education for nation-building. There are strong reasons for the state to be involved. First, market failure in education can be rectified by the state's intervention. Although neoliberal and the World Bank have advocated the state's nonintervention in markets, they also have recognized the necessity of the state's intervention when the market fails in education, particularly universal primary or secondary education (Ashton *et al.*, 1999). Second, the state can use education to serve state formation and development. Buchert (1998) argued that the purpose of education is to fulfill the broader social development goals stipulated by the state, predominantly those related to economic, political, social, and cultural developments that are determined by local, national, regional, and international contexts.

To be more specific, education in developmental states, as in other societies, addresses two major themes related to state formation: economic and sociopolitical. Human capital theorists see education and training as important means to acquire, accumulate, and enhance a society's resources. Schultz (1961, 1971) argued that people can invest in human capital through education and training to acquire knowledge and skills and that enhancing human capital can increase human performance and earnings, and, in turn, strengthen the economy and raise living standards. Becker (1998) used two Asian developmental states, Taiwan and South Korea, to illustrate that investment in human capital is a major way to encourage development and alleviate poverty. However, Blaug (1987) criticized human capital theory for overestimating education's contribution to economic growth; and, according to Livingstone (1997), the theory fails to recognize the multifaceted character of learning, particularly in knowledge-based societies. Despite these criticisms, Castells (1992) argued that the developmental state's ability to redefine its manpower needs and re-skill its citizens is key to achieving economic success. The World Bank (1993) has considered the increase in state's investment in education as an important impetus to East Asia's miraculous economic growth.

Based on the cases of the Four Dragons in East Asia, Ashton *et al.* (1999) proposed a skill formation model to explain how developmental states influence both education and the economy for development. First, the state can use trade and industrial policies to influence the markets in which companies compete and the economy's overall direction, thus influencing employers' demands for skills during specific times. Second, to ensure an appropriate match between the demand for, and supply of, skills, the state can use existing and future human resources requirements to guide its education and training systems. Third, to achieve this task, the state also has a strong control over educational and training institutions so that it can respond quickly to meet the labor market's changing demands.

Besides fulfilling economic tasks, education in developmental states is entrusted with sociopolitical and cultural tasks for state formation. In East Asia, values education has been seen to contribute to economic growth and to establish and sustain the state's political legitimacy and independence (Castells, 1992). Green (1997) pointed out that one major role of the education system is to spread the dominant cultures, foster a sense of nationhood or statehood (e.g., by generalizing the use of the dominant language or dialect), and develop and maintain social cohesion and political and cultural unity. In some developmental economies in East Asia (such as Singapore, South Korea, and Taiwan), one major impetus to emphasizing values education as a strategic component of development was external threats resulting from their "antagonistic or at least strained relationship" with a neighboring power (Morris, 1996: 96). To survive external threats, these developmental states used education to cultivate a collective urgency for rapid economic development and a strong and distinctive sense of national solidarity and identity.

Re-questioning the State's Role in Education and the Globalized Market

The developmental-state thesis can explain the upward mobility of developmental economies, such as Taiwan, from peripheral to semiperipheral status in the international economic hierarchy (Gold, 1986, 1988) and the stagnancy of developmental economies in Latin America (Gereffi, 1990). However, since the late-twentieth century, the developmental-state thesis, particularly its emphasis on the state's significant role in development and education in Asian economies, has been severely challenged by globalization, particularly after the 1997 Asian financial crisis.

The 1990s witnessed the development of a huge academic literature on globalization in various disciplines (Held *et al.*, 1998; Marsh *et al.*, 2006). The postwar period witnessed the conspicuous intensification and acceleration of the movement of people, capital, goods and services, information, and images across national borders. According to Giddens (1999), this spatial-temporal compression has affected various dimensions of human activities and even created new economic, social, and cultural areas that may transcend borders. This, in turn, has increased the interconnectivity and interdependence of states, economies, societies, and peoples.

There are multiple views on the relation between the state and globalization in development (Held *et al.*, 1998; Sorensen, 2006). Skeptics such as Hirst and Thompson (1996) have argued that the world is far from global and considered globalization as nothing but a myth. Radical scholars have contended that globalization challenges and undermines the states' power and autonomy and predicted some convergent effects of globalization on human activities, such as the "end of history" (Fukuyama, 1992), the "end of geography" (O'Brien, 1992), a "borderless world," the "end of the nation state" (Ohmae, 1990, 1995), and the death of the "national citizen" (Urry, 1998). Common to these predictions are emphases on the de-differentiation and even erosion of traditional borders, and the diminishing role of the nation-state and national governance. In particular, the state's power is doubly squeezed by shifting upward to regional institutions (such as the European Union in the case of its member countries)

or transnational or supranational agencies (such as the World Trade Organization), and downward to subnational, nongovernmental entities (such as large, private companies) (Delanty, 2000). Between the two extremes of skeptics and radical scholars are those theorists who both recognize the world's increasing interconnectivity and interdependence and argue for the nation-states' continuing key role, as well as their divergent responses to globalization on various dimensions, including economy, culture, and education (Currie & Subotzky, 2000; Green, 1999; Sassen, 2000, 2002).

Education scholars also have addressed the tension between convergence and divergence in response to globalization. Radicalists such as Usher and Edwards (1994) predicted the state's loss of control over education and the increasing convergence of education systems on global or regional norms. However, more scholars have argued for the coexistence of convergence and divergence. On the one hand, the changing global economy requires a redefinition of manpower needs and new skills formation, and therefore new imperatives for education. As Green (1999) observed, there is considerable convergence in policy rhetoric and objectives in education in many countries, including developmental states. Education also is regarded as a primary means of promoting "skills of globalization" for competing and living together in an increasingly interconnected and interdependent world (Marginson, 1999). On the other hand, nation-states, as Green (1999) argued, still control their education systems, and they differ in policy details, structures, and processes because of different national conditions (including political traditions and institutions, economic structures, and manpower planning) and different paces of development.

Developmental States, Globalization, and Nationalism: Japan and China

Japan and China illustrate the continuing significant role of the state in development and education and how education can be used for nation-building. In East Asia, Japan is a capitalist developmental state that belongs to the first generation of developmental states in East Asia right after World War II, whereas China is a socialist development state and belongs to the second generation. This section argues that both societies have dual phobias: the phobia of lagging behind other countries and/or being unable to sustain their development in the pursuit of global capital, and the phobia of losing their collective political identity while competing in an increasingly interconnected world. As a result, education in these two developmental states is caught in a dilemma between globalization and nationalism, specifically, between the economic task of education for equipping manpower for competition in the global economy and the sociopolitical task of education to preserve the collective political identity.

Japan and China as Developmental States

After opening its ports to Western powers in the 1850s, Japan began to industrialize and modernize. In early twentieth century, it became a regional military and economic power. Despite its military defeat in World War II, Japan achieved unprecedented economic growth between the 1960s and 1980s and became a world economic power.

Johnson (1982) identified four major factors that contributed to Japan's success as the first developmental state in East Asia. They included: a small and efficient state bureaucracy managed by the best talents available in the system; a political system that enabled state institutions to be autonomous, take initiative, and operate effectively; the state-private sector cooperation with the coexistence of market-conforming and state-intervention chemistry; and a state-related agency that shared the state's management responsibility in leading and implementing the state's development agenda, such as the Ministry of International Trade and Industry (MITI). However, in the 1990s, Japan's economy began to experience a considerable slowdown, which was further complicated by unemployment issues, the rapid advancement of an aging society together with low birthrates, and the challenges of the rise of the information society and internationalization (MEXT, 2001c). The Japanese state also worried about two related social trends: an overemphasis on respect for individual rights and an underemphasis on social duties and responsibilities, and young people's social disengagement by drawing away from society to their own worlds (MEXT, 2001a).

China started its development later than Japan. After assuming power in 1949, the Communist Party of China (CPC) officially transplanted the former Soviet model of a central, planned economy and socialism in the Chinese soil. Market forces were banned, and private ownership and the private sector were prohibited. However, in the late 1970s, China gradually began to shift its development strategy, in Martinussen's (1997) terminology, from a noncapitalist path to socialism (by dissociating from world economy and relying on a state-controlled planned economy) to a capitalist path to socialism (by adopting capitalist principles and a market economy) to create the necessary material conditions for socialist development. Liew (2005) argued that since the introduction of market forces into its socialist economy in the 1980s, China's pathway to rapid economic development has tended to fit the developmental-state type, rather than the liberalization models of the World Bank and the International Monetary Fund. China's state under the leadership of the CPC has actively mediated market reform and controlled the process of transformation from a centrally planned economy to a socialist market economy. In particular, China's state has adopted four major development strategies: using capitalist principles and market forces to revitalize its declining socialist economy; engaging in a deliberate and gradual shift of economic structure from the primary to secondary and tertiary sectors; letting some areas and people prosper ahead of others; and diversifying economic activity to pursue global capital and reduce economic protectionism (Law, 2006b).

In these two East Asian developmental states, education is used as a vital means to enhance the quality of their human capital and to serve as an important development tool for industrialization. In Japan, education has been regarded as an important engine, particularly for the postwar economic miracle. In the 1860s, Japanese national leaders began establishing public education with a view to using it to modernize Japan and catch up with Western industrial countries. Since then, prewar educational development has been designated as a most important national policy area (Kida, 1986). In the early twentieth century, Japan achieved universal primary education, established a selective multitracked secondary education system, and developed a highly selective, elitist higher education system. This educational investment enabled Japan to maximize its human resources by producing a massive educated and trainable workforce

and elite for catching up with Western countries (Schoppa, 1991). After its defeat in World War II, the Japan's state obtained its people's support for the nation's reconstruction through education (Kida, 1986). It extended universal education from six to nine years, and later expanded senior education and higher education. This became an important source of skilled labor force for postwar nation-rebuilding. However, Japan's education system has been criticized for high centralization because the state can exert considerable influence on local governments through the pressure of the peoples' strong demand for equal opportunity for education and the provision of standardized services to all citizens. The Japanese state uses three major measures to influence local school education: the Ministry of Education, Culture, Sports, Science and Technology's (MEXT) prescription of criteria and standards in curriculum through the Courses of Study; the disbursement of general educational grants to local governments and the granting of special national aid for various items; and the national contribution to half of salary expenditures of educational personnel, particularly in public schools of compulsory education (Kida, 1986).

Unlike Japan, China began using education to develop its human capital at a rather late stage. Despite Chinese civilization's long history, education in imperial China was limited to the elite and associated with officialdom. In 1949 (the founding year of the People's Republic of China), it was estimated that 80% of its population was illiterate. Despite an emphasis on vocational competence in nation-building, Mao Zedong held a low view of human capital and used the class struggle of the masses to fight against intellectuals and professionals, particularly during the Cultural Revolution (1966–1976). When Deng Xiaoping resumed power in late 1970s, he shifted from Mao's ideological approach to a pragmatic one. Deng (1977, 1978, 1985) saw education and science and technology as key to the nation's prosperity, advocated respecting knowledge and talents, and suggested that China's national strength depended on the Chinese workforce's qualifications and the quantity and quality of intellectuals. China also has a strong wish to use education to turn its huge population (1.3 billion in 2005) from a national liability to national asset (China's Education and Human Resource Development Project Team, 2003). To achieve this end, China's state adopted a series of strategies, including the speeding up of the campaign for eliminating illiteracy among people over age 15, and the introduction of universal basic education of nine years in 1986 to improve the basic literacy and skills for the labor force at the lowest, but largest stratum; the rapid expansion in the 1980s of the vocational track (and the corresponding reduction of the academic track) in senior secondary education to provide subprofessionals at the middle stratum; and the drastic expansion of higher education in the late 1990s to increase the quantity and enhance the quality of talents at the high stratum (Law, 2000).

The Economic Phobia of Lagging Behind, and Education Reform for Economic Globalization

Despite an emphasis on skills formation, some have questioned whether the education systems of Japan and China are capable of equipping students with the necessary abilities to face the challenges of economic globalization in the twenty-first century. Since the 1960s, many have wondered whether the Japanese education system could help

Japan become an economic power in the region and the world. In the late 1960s and mid-1980s, respectively, the Japanese state initiated two major education reforms to increase students' choices, reduce examination pressure, and deal with school violence and students' misbehavior (Schoppa, 1991). Despite the two reform initiatives, these long-standing issues remained unresolved and the general public was dissatisfied with the education system and school curriculum (Peter & Curtis, 2002).

During the third reform at the turn of the millennium, Japan admitted that its education was "deteriorating" (National Commission on Educational Reform, 2000). First, the Japanese education system was criticized for failing to prepare students to cope with social change, meet the new manpower needs and demands, and rise to the challenges arising from globalization and the rapid progress of science and technology (MEXT, 2001a). Second, Japan's students suffer from high examination pressure and information cramming (Bossy, 2000). Because of this, the Japanese school curriculum, as admitted by the Curriculum Council (1998), had not satisfactorily equipped Japanese children with an ability to study, make judgments, express opinions, and use different perspectives. Third, Japanese education faces some serious educational issues, including bullying and violence on campus, disruptive behaviors in class, truancy, and juvenile delinquency (MEXT, 2001c).

Similar to Japan, China admitted that its education system lagged behind changing social needs in the twenty-first century. First, the overall quality of the Chinese labor force is still low and has difficulty competing in the global knowledge economy. The average length of schooling for people over age 15 is about eight years and is three to six years shorter than that of developed countries and newly industrialized economies (Ministry of Education, 2004a). The population's average level of popular science and technology is far below that of Japan, the European Union, and the United States (China's Education and Human Resource Development Project Team, 2003). Second, many schools emphasize rote learning and drilling and focus on outdated book knowledge that is difficult for students to learn (Ministry of Education, 2001b). Third, on average Chinese students are "relatively weak in creativity, practical dimension, employability, and founding their own business" (Ministry of Education, 2004a: 46).

Despite the inadequacy of their respective education systems, the states of Japan and China continue to believe that education can prevent them from lagging behind others and help them sustain their development. In Japan, this strong belief is explicitly reflected in various education reform proposals and particularly the title of the 2004 education reform plan, *Japan! Rise Again!* (MEXT, 2005). In China, the *2003–2007 Action Plan for Invigorating Education* reiterated that education "is the very basis of the long-term development of the nation" (Ministry of Education, 2005: 1). To deal with external challenges from globalization and long-standing domestic educational problems, in the early 2000s, both developmental states began to reform their school curricula and shift from a skill-formation model to a model that emphasizes developing students' abilities to meet changing social needs.

Earlier in the education reform in the 1980s, Japan began to use education as a means to cope with internationalization, and tried to use globalization to justify the urgent need for education reform. The ad hoc National Council on Educational Reform (1985: 18) (which was established by Premier Nakasone) even warned that if Japan

wanted “to survive and develop in the age of internationalization, it is essential . . . [to] design [Japan’s] education reform from the standpoint of internationalization.” As observed by Lincicome (1993), this Council advocated the concept of “cosmopolitan Japanese” who can communicate in at least one foreign language, have a thorough knowledge of foreign countries and cultures, appreciate the cultures of other peoples, and have an international consciousness. A similar urgency to equip Japanese students to face economic globalization can be found in the 2001 Education Reform Plan for the 21st Century (also called the Rainbow Plan) (MEXT, 2001b). Parallel to this plan is the introduction of a new school curriculum reform in 2002. The Japanese state advocated a shift in pedagogy from a teacher-centric and textbook-centric approach to student-focused and self-directed learning, and it emphasized the development of students’ willingness to learn independently and their independence in thinking, making judgments, engaging in self-expression, and acting for themselves (Yoshikawa, c. 2000). In particular, students from grade three to grade nine are now required to take Integrated Studies, in which they can undertake their own research, go on field trips, and tackle real-life problems with hand-on activities.

In China, the curricular reforms of primary and secondary education are intended to strengthen the relevance of students’ study to their daily lives and modern social and technological developments; to help enhance students’ motivation to learn actively and their willingness to explore and develop various abilities (including the collection and processing of information, acquisition of new knowledge, problem analysis and solving, and collaboration and exchange); to equip them with the basic knowledge and skills of lifelong learning; and to help them develop a proper worldview and global outlook, in addition to developing a love for China, the ruling party, and Chinese cultures (Ministry of Education, 2001b, 2003).

Japan and China selected Information Technology (IT) and English as important transnational skills to be fostered among students for living in an increasingly connected world. The Japanese state is attempting to make Japan an internationally competitive nation built on IT (i.e., e-Japan) within the first decade of the third millennium (Information Technology Strategic Headquarters, 2001). The Curriculum Council (1998) encourages the implementation of consistent and systematic information education and the use of computers in class-learning activities at all stages of school education. In 2002, the Japanese state changed IT and Computers (including basic computer skills) from an elective to a compulsory subject in the junior secondary curriculum, and in 2003, it introduced a compulsory course in IT for all students in senior secondary schools. Unlike Japan, China has no plan to make itself an e-nation. Despite this, in 2001 the China started an effort to popularize IT education in school education within 10 years (Ministry of Education, 2000). By 2005, IT courses were offered in secondary schools across the nation and in primary schools in relatively developed areas.

In these two non-English-speaking developmental states, English is seen as a means to increase interconnectivity with the rest of the world and to enhance human capital in the pursuit of global capital. In the early 2000s, Japan wanted to equip “Japanese with English abilities”: speaking, listening, reading, and writing. The MEXT (2002) admitted that Japan’s development in the global economy had been hindered by a lack of

sufficient English proficiency. To rectify this, the MEXT (2003) issued the Action Plan to Cultivate Japanese with English Abilities. Japan has selected English as the major common foreign language for its children to master and expects that English-capable Japanese can help Japan link to the rest of the world, gain the world's understanding and trust, enhance Japan's presence in the international community, and improve its national development. Primary students are now provided with conversational activities. In the new Courses of Study that were implemented in 2002, English became a compulsory subject in junior and senior secondary education.

China recognized the significance of English much earlier than Japan. After reconnecting with Western countries in the late 1970s, China replaced Russian with English as one of the most important foreign languages, and students began to receive English lessons in junior secondary education. Because of the intensification of economic globalization and informatization, the Ministry of Education (2001a) recognized the increasing importance of foreign languages, particularly English, and set the learning and mastery of at least one foreign language as the "basic requirement of citizens in the twenty-first century." However, the Ministry of Education (2001d) deemed that the average English proficiency of the Chinese people has lagged behind the needs of national economic and social developments. Consequently, from 2001 English instruction began to be officially extended from junior secondary education to primary three across the nation (Ministry of Education, 2001a). Schools are required to provide at least four learning activities per week, cutting one lesson on Chinese language if necessary. Some urban areas, such as Shanghai and Beijing, have extended the provision of English lessons to primary one students. Three years later, the Ministry of Education (2004b) asked colleges and universities to reform the curricula of university foundation English for students whose major is not English language, with a view to enhancing overall English proficiency, particularly in listening and speaking.

The Sociopolitical Phobia of Losing National Identity and Revitalizing Nationalism in the Curriculum

In addition to an economic phobia, both Japan and China fear losing their collective political identities in the process of modernization and economic globalization. In response, they have reasserted the importance of preserving their collective political and cultural identity, in particular, by reviving nationalism in their school curricula. Despite the struggles for modernization since World War II, Japan had been proud of its national spirit and cultural traditions. However, whilst preparing its people for globalization, the Japanese state has feared losing its national characteristics and cultural identity. In the 1980s the Japanese state began to be aware of the increasing tension between being a "Japanese citizen" and being a "world citizen" (National Council on Educational Reform, 1985: 18). The Central Council for Education (1997) even expressed its fear that in the future, Japanese people may lack a sufficient understanding of traditional culture and the culture may be lost because of a lack of successors to perpetuate it.

Similar to, but more complicated than Japan, at the turn of the millennium, China, as a late developmental state, fears the loss of its socialist collective political identity. The rapid downfall of the former socialist block in the late 1980s and 1990s leaves

China as one of very few remaining socialist countries, and since then, this has created a national identity crisis for its people and the nation in the international community (Law, 2006a), which has been exacerbated by the ruling party's identity crisis. The change of development strategy (as described earlier) brought forth a series of domestic problems, such as widening gaps between urban and rural areas and between the rich and poor; intensified social unrest and conflicts; widespread materialistic values; and the widespread power abuse of party cadres and officials (including very top-ranked CPC members, such as Beijing's Mayor in 1995 and Shanghai's municipal party secretary in 2006, who were sacked for corruption). The massive student demonstration in Tiananmen Square in Beijing in 1989 represented the popular challenge to the legitimacy of the CPC's leadership and led to military suppression with the use of state force (Fewsmith, 2002). All these negative consequences of economic reform were deemed a serious threat to China's social stability and the CPC's political leadership.

To deal with their sociopolitical phobias, China and Japan revitalized their citizenship education. Since the 1980s, the Japanese state has attempted to deal with the global-national-local tension by reconstructing Japan as a culturally oriented nation in the globalizing world with a two-pronged approach. On the one hand, the Japanese state encourages schools to foster values related to global citizenship, such as a rich sense of humanity, respect for life and human rights, an appreciation of different cultures, a spirit of international cooperation, and living together in harmony. On the other hand, the Japanese state repeatedly promotes the concept of being Japanese more than global citizenship. In his address at a meeting on educational reform, Prime Minister Nakasone (1984) expressed that the education reform in the mid-1980s could help "preserve and further develop the traditional Japanese culture," improve children's moral and behavioral standards, and also prepare Japanese citizens "to contribute to the international community with a Japanese consciousness." Whilst promoting the digitization of education, the Japanese government attempts to reform its education system with a view to making a "culturally oriented nation" through helping students foster self-discipline, consideration for others, and a deep respect for traditional culture and social norms (MEXT, 2001c).

In particular, the Japanese state used two major means to reinforce and consolidate the sociopolitical function of education for preserving Japan's traditions and cultures. The first means to maintain the national identity of Japanese living in a globalizing world is to legalize this function of schools by amending the Fundamental Law of Education under the leadership of Prime Minister Koizumi (Akito, 2002). Per Koizumi's request, the Central Council for Education (2003) proposed to amend the law to emphasize the school's importance in fostering among students a sense of civic responsibility, a respect for tradition and culture, and love of the nation and home. In 2006, the Japanese parliament enacted a patriotic bill calling on schools to inculcate in students respect for tradition and culture and love for the nation and homeland.

The MEXT (2001a) used the curriculum as the second means to inculcate Japanese people with Japan's traditions and culture. Students are exhorted to deepen their understanding of, and pride in, national and local histories, cultures, and traditions (MEXT, 2000). To sustain Japan's traditional cultures, schools are urged to provide students with

hands-on activities in traditional arts and crafts and teach them traditional performing arts and traditional manufacturing techniques (Central Council for Education, 1997). To foster a sense of social collectivity and deal with the children's moral degeneracy, Japan's Education Reform Plan for the 21st Century (MEXT, 2001a) requires schools to teach children social rules and basic morals at every stage of their development.

In contrast with Japan, China used laws to enforce the sociopolitical function of education much earlier. Chinese laws stipulate that schools train and equip successors of socialist construction and pass on to them CPC-prescribed values, including the "five loves" (love of home country, people, labor, science, and socialism), and the "five-isms" (patriotism, collectivism, internationalism, communism, and dialectical and historical materialism) to combat feudal, capitalist decadent ideas (National People's Congress, 1995, 1999). Unlike Japan, which does not have drastic social transformation, in the 1980s China began to make a paradigm shift to a more accommodative framework for socialist citizenship by opening up to the world; recognizing the market as a lever of diversification and pluralization; reinstating law as an external regulating force; revitalizing virtues as an internal, self-impelling force of social conformity; and repackaging the ruling party as a political vanguard of all classes (Law, 2006a). As a result, China's state redefined its citizenship education curriculum and reasserted the importance of citizenship education in nation-rebuilding. It has a strong urge to make use of citizenship education to help students identify with the present socialist system and political system across the nation regardless of regional, ethnic, and cultural differences (Wan, 2004).

The paradigm shift of socialist citizenship in China is also reflected in the change of its citizenship curriculum by incorporating a multileveled framework with elements of citizenship from global, national, and subnational levels (Ministry of Education, 2001c, 2002). Despite having a more accommodative framework, more emphasis is placed on the national than global or local level. This is reflected in the textbook revisions for citizenship education in primary and secondary schools after the CPC National Congress drew conclusions about these sociopolitical changes in China in the mid-1990s and early 2000s. As compared with previous versions, these two revisions, as shown by Law (2006a), carry both continuities and changes. On the one hand, these political textbooks continue to help students recognize the CPC's paramount leadership in and the working class's contribution to socialist modernization; understand the meaning of national symbols (such as national flag and anthem); and learn about the self-sacrificing spirit of role models, such as Lei Feng and the Chinese people's courage in their fight against foreign aggressors. On the other hand, the revised political textbooks changed in ways that reflect the inadequacy of socialism in modernizing China. For example, they replaced the party line on class struggle with cooperation among people and the peaceful coexistence of different ethnic groups. The textbooks also shifted from totally rejecting Western modernization, cultures, and characters to accommodating them; changed from playing down Chinese culture to including Chinese classical stories and characters and designating some Chinese values as good, traditional ones (such as hard work, filial obedience to parents, and willingness to help others); and placed a new emphasis on the importance of personal efforts and continuous improvement and discouraged unhealthy materialistic competition. These changes

in political textbooks reflect socialist China's significant readjustment in rebuilding the relative positions of socialism, capitalism, endogenous traditional Chinese cultures, and contemporary values.

Conclusion

The various models of development share two common concerns: the relative role of the state and markets in development and the relevance of the development models of developed countries to their less-developed counterparts. The developmental-state thesis recognizes the contributions of both the state and markets to development, particularly their supplementary and complementary roles. The various interactions between the state and market forces and the strategies they use can yield different results, such as different forms of and paths to development, and different extents of development ranging from regression to progression. In this sense, the developmental state is dynamic rather than static. It is a "diachronic phenomenon" occurring in different forms over a long period of time, adapting itself to new forms in new epochs (Woo-Cumings, 1999: 15).

Despite the challenges posed by the discourse of globalization and the 1997 crisis of financial globalization in Asia, the developmental-state thesis is still a useful framework for explaining the dual (economic and sociopolitical) phobias of countries like Japan and China in the pursuit of global capital and the sustenance of their national identities, and how their states use the economic and sociopolitical functions of education to address the dilemma between globalization and nationalism. The cases of Japan and China support Krasner's (1999) view that although globalization has challenged the effectiveness of state control, it has not fundamentally transformed the state's sovereignty, nor has it qualitatively changed the state's authority. Increased internationalization and deregulation has not replaced nation-states with global actors or local states. On the contrary, like other East Asian developmental economies (Weiss, 1998), the states of Japan and China continue to be powerful actors in the international polity and economy. Instead of being maneuvered by globalization, states can actively use it as both a common hegemonic justification for, and an external impetus to, urgent reform of their education systems.

The cases of these two East Asian developmental states also support Sassen's (1999) argument that the global is embedded in the national. Global processes need to take place and be materialized within national borders. In the world economy, the new division of labor has not changed the fact that labor markets are still embedded mainly in national contexts (Abrahamson, 2004). States are still the ultimate guarantors of the rights of global capital and the protectors of contracts and property rights. In education, the state can redefine policies to shift the orientation of education from skills formation to the fostering and enhancement of students' basic abilities for living and coping with a changing society and market at domestic and global levels. The state continues to be a principal selector and translator of global imperatives for education, including proficiencies in the transnational skills of IT and English. Thus the selection and translation of global educational imperatives are mainly local processes that are subject to the constraints of local players and conditions.

Moreover, despite the adoption of a multileveled framework for citizenship curriculum, states can promote and emphasize nationalism more than globalism for their domestic purposes and needs. The intensification of interconnectivity and interdependence between economies and between societies does not necessarily marginalize the state's role in nation-building or rebuilding, nor must it bring forth an overwhelming homogenization of human activities into a limited number of patterns. On the contrary, in countries like Japan and China, the temporal-spatial compression of human activities can induce an intense fear about the possibility of losing collective political and cultural identity. This, in turn, can create an opportunity for states to reassert in their citizenship curricula the distinction of nation-specific political and cultural traditions from those of other states and peoples in a globalizing world. Highlighting the importance of recognizing and respecting other cultures and peoples can be seen as another way to reinforce the sociopolitical and cultural distinctions between "we" and "they."

In a changing world, states are arguably transitional and developmental. They face changing domestic needs and conditions, changing external challenges from other member states, or both. They can respond by proactively or reactively revising their strategies of development; modifying their social structures and institutions; adjusting the interrelationships among the state, markets, and society; and/or enhancing their competitiveness for international competition while maintaining cooperation with other countries. In an increasingly interconnected and interdependent world, societal politics and economies are increasingly intertwined, rather than separated, as are the state and market forces. Globalization can stimulate and reinforce both the convergence and diversity of human activities at the local, national, and global levels. On behalf of its people, economy, and society, the state plays a significant role in both negotiating globalization for domestic development and promoting nationalism for domestic social cohesion by establishing its distinctions from its counterparts in international competition.

THE DEVELOPING STATES AND EDUCATION: AFRICA

John Metzler

Introduction

In March 2007 the world joined Africa in celebrating the 50th anniversary of the independence of Ghana, the first sub-Saharan African country to gain independence from colonial rule. Recognizing this seminal event in modern African history along with the subsequent ushering in of the postcolonial era across Africa that began in earnest in the early 1960s, it is an opportune time for a critical retrospective on the place and role of schooling (formal education) in postcolonial African nation-states. This critical review will be undertaken without adopting either an *Afro-pessimism* or an *Afro-optimism* perspective that dominates contemporary discourse on Africa (Ayittey, 2002; Bayart, 1993; Chabal & Daloz, 1999; Hyden, 2006); Rather an attempt will be made to couch this critical review in a broadly *Afro-realism* perspective.

In the early 1960s at the beginning of the postcolonial era in Africa there was consensus regarding the role of formal education in Africa's political, economic, and social development and the achievement of human "progress." Importantly, this consensus was shared by external actors such as the former European colonial powers, and the US through their bilateral aid programs, and the UN (UNDP, UNESCO, and UNICEF), the World Bank, and Western academic "experts," on the one hand, and leaders of the nascent (postcolonial) nation-states, on the other hand. This consensus asserted that formal education was an essential, and to some policy actors the most powerful/effective instrument in the struggle for economic and social development, political unity and the capacitation of the nascent postcolonial states, generating modernity, creating the "new man," broken of *his* primordial, traditional, worldview, interpreting the world and acting in the postcolonial era as modern men (a recognition of the importance of women and gender was delayed until the 1990s). (Almond & Powell, 1966) This perspective, albeit from a utilitarian as opposed to a theoretical perspective, was not a monopoly of the international and governing elite, but was fully embraced by the vast majority of postcolonial citizens who aspired for formal education for themselves and their progeny, perceiving schooling functionally, as the most important instrument in their struggle for economic advancement, prosperity, and socioeconomic security.

A consequence of the education consensus in the past 45–50 years, postcolonial African political regimes across Africa allocated more money to support the educational sector than any other sector with the exception of defense and security

(and in many states more than to defense and security). In 2007, what do African citizens and African nation-states have to show for this endeavor? The results in a number of Africa countries are impressive in terms of increased access to all levels of formal education, but are not as impressive when examined against the *promise* held out for schooling 50 years ago at the dawn of the postcolonial era in Africa. In the political arena in spite of an impressive movement toward democratization and political renewal, Africa is also plagued by *decayed and failed states*, authoritarian rule, ethnic strife, civil wars, and corruption.

In the economic arena Africa continues to be the poorest continent in the world, in spite of impressive growth rates at the national/macro level, upwards of 70 per cent of the population in subcontinent exist on less than \$2 per day. Socially, Africa today is the most unhealthy region in the world with the highest infant and maternal mortality rates, malnutrition, chronic malaria, in addition to being the epicenter of the global HIV/AIDS pandemic (Barnett & Whiteside, 2006; Poku & Whiteside, 2004).

In spite of this record, the faith placed in schooling by ordinary citizens and state regimes and international actors has not diminished or wavered. This can be demonstrated in the Millennium Development Goals that target universal primary education in Africa as a primary goal, and in the pride of place given education and training in targets set by the *New Economic Partnership for African Development* (NEPAD) and the African Union (AU). However, there is a growing realization on the part of both external (international) and internal (domestic) stakeholders that while formal education plays an essential supporting role in promoting development, the efficacy of schooling is not what was purported five decades ago.

How are we to make sense of the “failure” of schooling to realize its developmental rationality in Africa? The “answer” to this query is not easy or simple, reflecting the complexity of Africa’s colonial and postcolonial social, economic, and political realities. However, the first essential step is recognition of historical legacy of colonialism.

The Colonial Legacy: Ambiguities of Colonialism and Schooling

In order to understand postcolonial education processes and practice in Africa, it is essential to examine the legacy of colonialism (a) politically, economically, socially, and culturally, and (b) in the colonial education systems.

African societies varied in terms of precolonial education practice. However, it is important to recognize that all societies had sophisticated systems of informal education that allowed for the intergenerational transmission of knowledge, skills, values, and system of beliefs, all of which facilitated the reproduction society across time and space. Some African societies had sophisticated systems of apprenticeships, and others systems of religious schools which taught literacy and numeracy as exemplified by Quranic schools throughout Islamic Africa and church schools in Ethiopia.

Formal education and schooling in most of Africa was a consequence of Europe’s engagement in the subcontinent, most particularly during the era of colonial rule (1880s-

1960s). However, it should be noted that as early as the sixteenth century that Portugal had established a presence in coastal West Africa, that included the establishment of Christian missions and schools, most significantly in the Kongo Kingdom. This early era of European contact with sub-Saharan Africa that was characterized by active engagement by both Africans and Europeans (Thornton, 1992) was superseded by the onset of the trans-Atlantic slave trade initiated in the sixteenth century that resulted in great devastation of African societies in addition to immeasurable personal suffering among those directly affected by slave wars, capture, the “Middle Passage,” and enslavement in the Americas before slavery was effectively ended in the early nineteenth century.

Reasons for Colonialism

As I will argue, to understand the lasting legacy of the colonial experience on the processes, practice, and efficacy of schooling in postcolonial Africa, it is important to take brief cognizance of the rationale and subsequent practice of colonialism in Africa.

Economic Rationale for Colonialism

Industrial capitalism in Western Europe by late nineteenth century had become increasingly dependent on non-European markets for its industrial goods. Secure (noncompetitive) new markets for industrial goods were perceived to be essential to the survival and continued profitability of industrial companies that were for the most part located in European countries. Relatedly, for industrializing European countries which were resource-poor, or whose natural resources were rapidly depleting, secure (noncompetitive) sources of raw materials to supply the continued industrial/capitalist expansion was an imperative.

An additional economic rationale is associated with the averred crisis of over-accumulation. This Marxist perspective, associated most closely with Luxemburg and Lenin, asserted that contradictions within industrial capitalism resulted in an accumulation in profits that could not be absorbed in Europe, requiring colonial expansion (imperialism) to ensure safe locations for investing accumulated profits.

Political Rationale for Colonialism

Colonialism in Africa is closely related to rise of the nation-states in Europe and subsequent nationalism in the nineteenth century. More specifically, the unification of Germany and Italy, Republicanism in France, and associated European wars exemplified political tensions in Europe. The colonial endeavor in Africa (and Asia) was directly related to the political environment in Europe and to competitive nationalism. National prestige played directly to the competition for and rapid colonization of Africa—the Scramble for Africa—between 1885 and 1910. Political historians, such as Robinson and Gallagher (1968), argue that the colonial enterprise allowed for “peaceful” competition between European nation-states that actually delayed the onset of World War I until 1914. The national prestige afforded by colonial empire was enormous; European colonial powers could boast empires in Africa and Asia that spatially and demographically multiplied their size many times over.

Social and Cultural Rationale for Colonialism

The colonial endeavor in Africa was actively facilitated by social and cultural variables. Western Europe and the US experienced a revival or a renewal of Christianity in the nineteenth century popularly referred to as the Great Awakening that resulted in active Christian mission engagement in Africa and Asia. The imperative of the “great commission” to convert non-Christian populations in distant lands inspired “mission societies” to establish mission outposts throughout Africa. Mission societies were generally strongly supportive of the colonial endeavor, believing that the establishment of colonial authority would create an environment necessary for the realization of the mission agenda.

There were also secular perspectives that lent important ideological support for the colonial endeavor. Social Darwinism provided a “scientific” mandate for imperialism: Europeans as the superior *race* had a *natural* right to conquer and govern the *lesser races* of Africa. Moreover, this right was seen as an obligation—“the white man’s burden”—to “civilize” African societies and individuals.

These economic, political, and sociocultural factors, while potentially contradictory, converged to provide the structural impetus that resulted in the *Scramble for Africa*—the colonization of Africa between 1885 (Treaty of Berlin) and 1910. During this 25-year period, the entire continent of Africa was Balkanized into 51 European colonies; only Liberia and Ethiopia escaped direct European colonization. But, how do these variables relate to formal education and schooling in Africa? Is there anything within the rationale for colonialization, other than the Christian mission imperative, that lends itself to the initiation and expansion of schooling in Africa? To address this question systematically, it is essential to analyze the actual practice and structures of colonialism in Africa. However, the structures and practices put in place by the colonial endeavor were informed by the rationale for colonialism.

The Structure and Legacy of Colonialism and the Colonial State

To understand European colonialism in Africa it is essential to keep in mind that while burgeoning European nation-states were among the most powerful in the world at the end of the nineteenth century, they did not have limitless, political, economic, and military resources. National treasuries were depleted by chronic warfare, and as European states responded to the growing welfare needs of their own citizens caused by rapid industrialization and urbanization. These financial and political realities impacted on and limited the structure of colonial practice in Africa resulting in two cardinal agendas of European colonialism in Africa (with the exception of settler colonies such as Kenya, Rhodesia, and South Africa).

Firstly, revenue generation, where each colony was responsible to pay for itself—all expenditures by the colonial state had to be generated locally via taxation of colonial subjects, commercial concerns, and primary extractive industries—mining and agricultural. Yet, this latter source of revenue was curtailed by the symbiotic relationship between the colonial state and colonial capital. This imperative is central in understanding the nature of the support—or *lack thereof*—by colonial regimes for schooling.

Secondly, the establishment and maintenance of sovereignty and security were the primary, some historians would argue the sole, political imperatives of colonial regimes. Absent from the colonial state agenda was any concern for state legitimacy within the colonies, such as addressing human welfare concerns and the development of social and communication infrastructures, including support for schooling, so important to the modernizing European state. However, these concerns or obligations were clearly outside of the purview of the colonial state.

As a consequence of these limiting imperatives, the colonial state in Africa was imbued with contradictions, the state was maximalist in terms of security (developed police and armed force relative to other state apparatuses) and revenue collection, but minimalist in all other areas of state function with a very underdeveloped bureaucracy particularly in areas of human and social services: health care, education, housing, water, sanitation, developing transportation and communication infrastructure, and support for the development and diversification of the economy, all of which are central behavioral characteristics of modern states (including capitalist states). Moreover, the lack of revenue and state capacity, combined with the imperatives of hegemony and security led to employing strategies to weaken potential internal opposition (divide and rule) and to govern through ethnically and regionally based “traditional authorities” (indirect rule). These well-established colonial practices have had a long term, and often devastating, impact on postcolonial nation-states (Mamdani, 1996; Cooper, 2005).

The modern state as exemplified by the geopolitical north regardless of political ideology or orientation, views formal education, in the form of state-supported schooling, as an essential political instrument (Allthuser, 1971; Bowles & Gintis, 1976; Carnoy, 1984; Gutman, 1987; Katz, 1975; Spring, 1985). The skills and knowledge necessary to administer the state in all its permutations are dependent on an effective educational system. Moreover, the state is committed to supporting and facilitating economic productivity and growth, which in turn is dependent, *inter alia*, on a skilled, flexible, and creative workforce—a product of an efficient and flexible educational system. And, finally, the state through political socialization intended by schools enhances state and political system legitimacy.

For the most part the colonial state did not share the attributes of the modern European state that fostered state support for education. The underdeveloped nature and scope of the colonial state resulted in a limited demand for skilled bureaucrats, except in the area of state security and to provide the very basic functions. Moreover, the realities of the colonial mode of production (articulated below) made minimal demands for an educated and skilled workforce. And, finally, until late in its tenure, legitimacy was not a priority of the colonial state (Cooper, 2005; Mamdani, 1996; Young, 1994).

Given these factors, there was only a limited political imperative for supporting formal education/schooling in most African colonies. Consequently, until the late colonial period there was very limited colonial state support for schooling. In the case of settler colonies, where the settler state apparatuses supported the settler hegemonic imperative, state support of education was even more parsimonious, and it severely restricted schooling provided by nongovernmental agencies, most specifically Christian missions.

Legacy of the Colonial State

At independence the postcolonial state inherited a long-lasting legacy from the colonial state which necessitated active state engagement (largely absent in the colonial era) in promoting social, economic, and political development while, concurrently, severely limiting the options available to the nascent regimes. This political legacy can be briefly summarized in the following manner.

First, the postcolonial regimes inherited states that were often devoid of nation. The lack of political capacity and the need to weaken internal opposition to colonial rule had forced the colonial state to govern through various schemes of “divide and rule” that resulted in ethnically defined and divided colonial states. Consequently, postcolonial leaders were confronted with the gargantuan task of developing national identity—a task not easily accomplished given the states’ limited political and economic capacity. Consequently, ethnicity has been a major issue in most postcolonial states in Africa.

Second, postcolonial regimes inherited state structures that lacked democratic political culture and institutions. Indeed, colonialism by definition and practice was antidemocratic. Other than formalized structures of elections, infused at independence, there was no established legacy of a culture supporting democratic values. In the absence of a democratic political culture that, *inter alia*, valued basic human rights and tolerated political opposition, it was almost natural for under-capacitated postcolonial state regimes to resort to colonial-like authoritarianism in dealing with internal opposition.

Third, the underdeveloped state capacity greatly limited the ability of the new postcolonial regimes to meet the legitimate aspirations of their citizenry. In most African nations the state lacked the bureaucratic and financial capacity to develop, initiate, and administer programs to enhance social well-being of citizens (health, education, housing, sanitation, etc.) and to stimulate economic productivity and development. Because of underdeveloped colonial education systems, postcolonial states inherited a very limited supply of educated, skilled, and experienced bureaucrats, who would be essential to realizing the development imperative of the new nation-states.

Fourth, the postcolonial states inherited an overdeveloped, relative to the rest of the state apparatus, security capacity in the form of the national police and armed forces. Consequently, it is not surprising that, early on, some postcolonial state regimes turned to these apparatuses when they faced crises of legitimacy; nor, is it surprising (although very unfortunate) that the armed forces, privileged in the colonial era, are in the position to stage successful coups when inaugural state regimes are unable to govern effectively, or meet the legitimate aspirations and needs of the citizenry.

Legacy of the Colonial Mode of Production

As indicated above, the colonial imperative not to spend more than it could raise through local taxes greatly restricted revenues available to the colonial state for the development of social and economic infrastructure, while concurrently facilitating and enabling colonial capital (i) to extract raw materials and profits from the colony with little or no horizontal reinvestment in the colony and (ii) to guarantee market monopolies for manufactured goods through deliberate disincentives to local industries.

More specifically, colonial economic policy led to the identification of a single (usually only one) source of revenue/expropriation resulting in the creation of what economists have termed *mono-economies* that are extractive in nature, such as mining, agricultural (large-scale commercial farms in some colonies and forced peasant production of export crops in other colonies). These export-oriented raw material-extractive industries most often made no attempt to process the minerals or agricultural products in the colonies before exportation. Consequently there was little or no horizontal multiplying effect from the extractive industries. There was also no diversification of the domestic colonial economy.

As a consequence of the distorted nature of the colonial economy, there was little or no development of infrastructures for communication, transportation, and financial services, other than what was needed to facilitate the expropriation of primary product(s). Road and rail systems ran from location of raw materials (e.g., where the mines were) to the coast, with limited development within the country. Moreover, until the late colonial period there was no state support for developing local African entrepreneurs with little or no access to credit and other vital financial services. Indeed, in settler states African entrepreneurship was actively discouraged for fear of competing with European settlers.

Economic Legacy

The economic legacy of colonialism has been, if anything, more severe than the political legacy. The export-oriented extractive mono-economies of the vast majority of colonies in Africa resulted in the institutionalization of distorted capitalist systems which structurally hindered the development of market-driven (or centrally planned) diversified productive economies able to take advantage of Africa's rich potential and opportunities afforded by the increasing globalized world economy. Consequently the majority of postcolonial African governments were revenue-poor, with insufficient funds to expand woefully underdeveloped infrastructures, or to meet the legitimate demands for expanded social services on the part of their citizenry.

This economic legacy has had a direct impact on the schooling in postcolonial Africa. Most obviously, the lack of revenue precluded the rapid expansion of formal education, muting the popularly held assumption that schooling was essential for productivity and economic development. Less obvious, but just as detrimental, I would argue, has been the expansion and institutionalization of a system of schooling that is orientated to the realities of the distorted colonial mode of production. Jobs in postcolonial Africa, as in colonial Africa, have primarily been in the public service sector, informing and rewarding a system of schooling that eschews creativity, problem-solving, and entrepreneurship.

Social and Cultural Legacy of Colonialism

The social and cultural legacies of colonialism were not uniform throughout Africa. In a number of colonies urbanization was rapid in the late colonial period. This is particularly true of mineral-based economies such as Congo and Northern Rhodesia (Zambia). However, a number of Africa colonies remained overwhelmingly rural. Social and cultural dislocation was not as severe in these colonies as it was in more

urbanized colonies. But, there were rural-based colonies, such as Malawi in south-central Africa and Burkina Faso in West Africa, which suffered significant social dislocation as they served as sources of cheap labor (labor migration) for the mining and plantation economies in neighboring colonies.

The colonial endeavor, as I argued above, above, was cultural as well as economic and political. Colonialism depended on an ideology of racial and cultural superiority that legitimized the practice of gross discrimination and oppressive regimes, not just to the colonizers (and citizens of the metropole), but also to the colonized. Colonial cultural apparatuses—including schools—were engaged in a dual cultural strategy of glorifying European culture while concomitantly denigrating African culture, values, and worldviews. The *success* of this strategy in terms of what Franz Fanon, among others, has termed the *colonization of the African mind*, is, many would argue, an ongoing legacy of colonialism and the colonial education system (Fanon, 1963; Carnoy, 1974; wa Thiong'o, 1986, 1993).

Schooling and Formal Education in Colonial and Postcolonial Africa

Colonial Educational Policy and Practice

There is a large, albeit uneven, scholarship on colonial education and schooling in Africa. Much of this scholarship has focused on the role of European and North American mission societies in the establishment and expansion of formal schooling throughout Africa. Sybille Kuster (1998, 330–369), among other scholars, provides a comprehensive bibliography of academic work on colonial education in Africa. However, it is beyond the scope of this chapter to critique or to even attempt to summarize this literature. Instead, I will attempt to provide a critical overview of colonial schooling as it was articulated differentially throughout diverse colonial milieus and its consequential institutionalized legacy for postcolonial African states.

Critics of colonial education policy and practice in Africa highlight two major, and potentially contradictory, shortcomings: a sin of omission—parsimonious resources allocated to schooling in most Africa countries; and a sin of commission—the deliberate use of schooling (curriculum, school structure, cocurricular activities) to *colonize* the minds of and *mis-educate* African pupils. Indeed, with a few notable exceptions, at independence African colonies inherited school systems that catered for a small percentage of the school-age population, putting into question the efficacy of schools as colonial ideological apparatuses beyond the creation of a small educated elite who were destined by, *inter alia*, their educational credentials, to be leaders in postcolonial African states. While the long-term negative impact of inherited and internalized ideology on African education is important to recognize, of more lasting negative legacy is the institutionalization and structuration of a colonial education system. This system reflected the realities of colonial political systems that were undemocratic to the core and that were structurally antithetic to state intervention in social and economic development. Hybrid colonial capitalism precluded meaningful state intervention in the economy, the “freeing” of market forces, and the unleashing of an entrepreneurial spirit.

The political and economic realities of African colonialism produced an ecology that shaped and restricted educational practice in the colonies in ways that challenged the goals and agenda that various stakeholders set for schools. However, the actual development and institutionalization of colonial education practice was shaped by the interplay or dialectic between the central stakeholders, as they sought to realize their goals for education, and the restrictions imposed by the realities of the colonial political economy. Therefore, to understand the structuration of a potentially dysfunctional education system it is important to understand how the major colonial stakeholders engaged educational policy and practice. By necessity this summary is a generalized overview that cannot take into account the diversity of educational experience in colonial Africa.

Colonial State

The perspective of the colonial state toward schooling for Africans was shaped by two imperatives: revenue and state efficacy. Given severe revenue restraints (outlined above), schooling, which was a drain on state treasury, was not perceived to be a priority until late in the colonial era. This tendency might have been challenged if revenue generation had been dependent on a diversifying economy that needed a permanent skilled workforce. But, as outlined above, the predominant colonial mode of production was primitive and extractive, depending on cheap, unskilled, and often migratory labor. Consequently, significant expenditure on schools for the development of a skilled or *disciplined* workforce was not a necessity for the realization of the colonial agenda. However, the colonial state apparatus—aimed at effective and efficient government—was dependent on a small, but growing over the course of the colonial era, supportive cast of African state functionaries or lower-level bureaucrats: clerks, translators, teachers, health assistants, and most importantly for state security, police and soldiers. This need was limited by the narrow capacity of the colonial state—hence, need for schooling was not great. Settler colonial states, such as South Africa and Southern Rhodesia were even more stingy with allocations to education. Importantly, at the eve of independence, the colonial state in all colonies was by far the largest employer. Colonial education systems reflected this reality, orienting curriculum and practice to meet the needs of a state-centric employment economy.

Colonial Capital

The colonial mode of production made very limited demands prior to the late 1940s for skilled labor. Extractive mineral and agriculture activities did not demand a literate and numerate workforce. Hence, unlike the situation in late-nineteenth-century industrializing North America and Europe, colonial capital did not advocate for mass-based public education in the African colonies in the absence of the need for a stable, skilled, and disciplined workforce. This would change in many African colonies in the post-World War II era, as development in the economy demanded a more rationalized, stable workforce. However, even in colonies that underwent this change, employment opportunities continued to be centered in the state apparatus, thus school curricula were not significantly reformed to meet demands of a potentially diversifying economy.

Missionaries

In most African colonies, schooling (other than Quranic schools) was the domain of missionaries and mission societies. Colonization of Africa coincided with the religious Great Awakening in Protestant circles in North America and Western Europe. The Christian missionary endeavor was informed by a duty to convert “native pagan” populations. The mission agenda has been summarized by the three “Cs”—Christianity, commerce, and civilization which were perceived by Protestants (and Catholics) as essential to Africa’s “escape” from “depths of paganism.” Unlike the colonial regime and colonial capital, missionaries viewed basic schooling as essential to realizing the three Cs. To realize this agenda missionaries adopted a basic curriculum centered on the four “Rs”—reading, ‘riting, ‘rithmetic, and religion (Metzler, 1988).

However, in spite of their intentions, given severe financial constraints, mission education only reached a small minority of the school age populations in the African colonies. While mission societies administered the vast majority of schools in sub-Saharan Africa, they were dependent on the goodwill and largesse of financially hamstrung colonial states.

African Responses

The response of Africans to the colonial education agenda was not uniform; it varied across space and time. But generally, Africans were suspicious, viewing and accepting mission schooling as it was perceived to be of instrumental/functional value to Africans, individually or as a specific group. In the mid-colonial era, as they were pulled into the colonial economy, Africans perceived the value of certain types of schooling as instrumental in achieving economic security and relative prosperity. Acting rationally, they advocated for *book learning* (as opposed to *adaptive* education promoted by the missionaries) that would provide the credentials necessary for employment in a job market dominated by the state apparatus. In this way Africans actively engaged and participated in the structuration of educational practice in colonial Africa.

Educational policy and practice that evolved dialectically out of the interaction of these interests were not uniform across colonial powers (French, British, Portuguese, and Belgians had different perspectives on schooling/education in colonies), or by type of colonialism (settler colonies, protectorates, and traditional colonies approached the issue of schooling differently).

Dialectics of Colonial Educational Practice

From the beginning of the educational endeavor in colonial Africa, a central question and area of debate focused on the curriculum—that is, what is to be taught? There was no neat and simple solution to this question. The French tended to take an elitist position—only a few selected colonial subjects would receive schooling that mirrored French policy of *assimilation*. The Portuguese followed a similar pattern, but were less generous than the French. The British, at first were supportive of a more broad-based education with a curriculum that was based on actual realities (as they perceived them) of African societies. The Belgians in the Congo (and in Rwanda and

Burundi) supported mission societies in providing primary education for as many children as financially possible, but their policy of Paternalism did not view Africans as needing, or being capable of, secondary or higher education. Consequently, at independence in 1960, Congo, a country the size of Western Europe, had less than 50 university/college graduates.

Settler colonies (South Africa, the Rhodesia, Kenya, Angola, and Mozambique) had a considerably different orientation. Generally suspicious of schooling for Africans, settlers perceived the potential for educated Africans to mount a political challenge and to compete with whites for skilled and professional jobs. Consequently, education for Africans in settler colonies was generally more restricted than it was in other colonies.

Case Study: Adaptive Education (British Colonies)

A brief case study of the thwarted *Adaptive Education* initiative undertaken by the British in the 1920s and 1930s will illustrate the difficulties in developing an alien education system that was in basic contradiction to the realities of the colonial regime.

Missionaries (primarily Protestant) had a vision of providing an education that was *adaptive* to the realities/needs (as they perceived them, of course) of the African societies. Consequently they promoted curricula that would promote social and economic development within rural communities. Adaptive education was itself an adaptation of educational policy and practice for freed slaves in the south US immediately after the Civil War, as exemplified by the work of Booker T. Washington.

In response to missionary encouragement, the British Colonial Office endorsed the Phelps-Stokes Commissions to British colonies in Africa (three in the 1920s). These reports were the most developed articulation of *adaptive education* as envisioned in Africa. The commission reports advocated the development and implementation of curricula that would promote:

- Character development—reflected missionary perception that African cultures were defective, and proper schooling would help overcome the influence of traditional African culture and promote character traits necessary to realize the three Cs in African communities (Jones, 1925: 265)
- Health and hygiene—promote preventive behaviors
- Productive skills related to the environmental realities of local communities—agricultural skills for *scientific farming* and “industrial” skills, such as carpentry, masonry, metal-smithing, furniture making, tailoring (for males), and needlework, nutrition, and mothering-skills (for females) (Jones, 1925: 265)
- Improved family life—care and discipline of children, establishment of “Christian Homes”—change in gender roles and relations, architecture, and spatial organization of living and sleeping arrangements—“the Christian home is the most essential organized unit of civilization” (Jones, 1925: 266)
- “Healthy recreation”—great suspicion of African entertainment—music and dancing as being hindering character development at best, and promoting paganism at worst—to be replaced by organized sport—this ties into the Victorian view of school sport as essential tool in character development (Jones, 1925: 267)

Reality of Practice

In spite of strong rhetorical support from mission societies and the British Colonial Office, *adaptive education* (like other mission initiatives elsewhere in Africa) was not implemented. Schooling throughout colonial Africa did not easily follow policy due to structural/systemic contradictions and ambiguities both within the political economy and educational practice.

The realities of the colonial treasury insured that funding was not available to realize even the most modest of educational goals. In spite of rhetoric that colonialism would bring development and “civilization” to Africa, economic realities of lack of revenues available to colonial states and to mission societies made schooling a luxury in even the most well-off colonies such as Ghana and Nigeria.

Just as importantly, educational initiatives, such as adaptive education, faced sustained resistance by African populations. This opposition was not to the idea of schooling; in fact by the 1930s schooling was perceived to be instrumentally necessary to personal advancement. Rather, opposition was focused on the lack of access, but also on the curriculum. Colonial subjects realized that *adaptive education* would not result in opportunity given the realities of the colonial political economy. There were only very limited opportunities for rural entrepreneurship (the focus of *adaptive education*). Only the expansion of “book learning” or academic education would result in economic advancement and security within the colonial political economy. Secure jobs, such as they were, were located almost exclusively in the government sector, not in the private sector, particularly, not in the agricultural or rural sectors.

To summarize, the colonial education systems that developed in Africa were alien. This was not the case in late-nineteenth-century Europe and North America where mass-based public education systems developed organically, but with significant contestation, out of the social, economic, and political milieu of these national communities. However, in colonial Africa schooling was an alien import, absent of any organic *connective tissue* with the host societies. Schooling was viewed by the colonial state and missionaries as an important instrument of the imperial enterprise. Consequently, they formulated educational policy, envisioning very specific roles for schools in realizing the larger colonial endeavor. However, the realities of colonial practice, and importantly, the active engagement of African people in the articulation of actual educational practice, helped shape and structure hybrid education systems that were reflective of the realities of African colonialism, but systems that would potentially have difficulties responding to the economic and political imperatives of postcolonial societies.

Postcolonial State, Nation-Building, and the Imperative of Schooling

In spite of the dismal colonial record there was a great deal of optimism 50 years ago as the first wave of formal African countries achieved political independence. Within Africa formally subject peoples and their nascent governments anticipated that the end of formal colonial rule would usher in an era of real political power that in

turn would facilitate socioeconomic development, opportunity, and prosperity. This sanguinity was shared by world leaders and by an incipient cadre of international development experts.

This early optimism was fueled in part by a strong faith in the functional power and efficacy of formal education. International development and education experts, from across the ideological spectrum and representing multiple disciplinary and theoretical perspectives shared a consensual orthodoxy that held that formal education was an essential (some averred, determining), if not sufficient, ingredient for political, social, and economic development in Africa.

This orthodoxy was based on two central assertions: (1) that schooling is an inalienable human right of all human beings; and (2) that an educated citizenry is *sine qua non* for political, social, and economic development. This consensus was fully endorsed by all the newly independent state regimes which viewed schooling as producing economically productive citizens, who in addition to providing the human capital essential to economic development, would assist a severely underdeveloped state structure by providing an adequately skilled bureaucracy with the expertise necessary to creatively address the gargantuan development project of the postcolonial state. Very importantly, this education orthodoxy was universally shared by the highly politicized citizens of the newly postcolonial nation-states who were convinced that improved access to all levels of education was essential to improving their own, and their progeny's, living standards (Fagerlind & Saha, 1989).

A definite causal link between schooling, human capital, and economic development was strongly asserted by Nobel Economic Laureate Theodore Schultz (1961, 1963), among many eminent international economists. Other social scientists avouched a similar relationship between the expansion of formal education in postcolonial African nation-states and the development of efficient political systems that were democratic and that were capable of responding to the legitimate demands of an engaged citizenry and in developing and implementing effective social and economic policies and programs. More specifically, scholars like Almond and Powell (1966), Coleman (1965), Rostow (1960), and Zolberg (1966) argued that schooling was essential to the creation of citizens free of primordial ties and values and who have a primary identification, not with "tribe" or ethnic group, but with the nation-state; a citizenry ready to be actively engaged in the agenda of the incipient postcolonial nation-state. Schools—which by their definition were *modern*—were the only institution with the potential to create *modern men* willing to break their ties to stifling traditions. Interestingly, it was only in the late 1980s that the education of girls and women was given priority by Western experts and donors.

The nascent postcolonial African regimes also had definite political rationales for expanding formal education. First, there was the imperative of national unity. The vast majority of postcolonial African nation-states are multiethnic, multilingual, and multi-religious. Colonial regimes had purposefully accentuated difference through policies of *divide and rule* and indirect rule. Consequently, with a few exceptions (such as Botswana, Lesotho, and Swaziland) African nation-states came into existence with no organic sense of identity with a *Nation*. Nationalism had to be created and fostered if political development was to be achieved and if political chaos or disintegration was to

be avoided. There were no natural institutions within civil society available to generate national identity and loyalty. Hence, schools (along with mass communication, particularly radio and local-language newspapers) were considered to be vital instruments in realizing the imperative of national identity and loyalty. Consequently, civic education became a core component of postcolonial school curricula throughout Africa. To further the political functionality of schools, in many African countries schools were mandated to host overtly partisan (pro-regime) political *clubs* that promoted identification with, and loyalty to, the extant regime.

Secondly, the new governments recognized that schools were essential to the expansion of state capacity. The inherited colonial state structure severely lacked capacity, particularly relative to the huge social and economic tasks it faced. The development and maintenance of “modern” social, economic, and communication infrastructure was dependent on an educated and appropriately skilled bureaucracy. Consequently the rapid expansion of formal education was essential to meet the demand for skilled state functionaries.

Thirdly, postcolonial regimes came to power with considerable popular support. These regimes were interested in maintaining this legitimacy. Support for regimes—regime legitimacy—however, was dependent on their ability to address the significant aspirations held by the nascent citizenry. Among the most popular of these aspirations was the expansion of formal education opportunities (for reasons given above). Failure to deliver on education (along with other social infrastructure like health care, housing, sanitation) would be disastrous to the legitimacy of new regimes.

Finally, on the political front, not unlike Western social scientists who were convinced of the importance of *modernity*, many first-generation postcolonial African leaders also believed that realization of economic and political goals was dependent on the creation of a “new man” among the citizenry. Interestingly, this was most true in countries that attempted to follow a quasi-socialist model of development such as Guinea, Mozambique, and Tanzania. Schools were the primary institution for the creation of the “new man” whose worldview, values, and perceptions were consonant with the regimes’ modernizing agenda.

Cultural Development

Postcolonial regimes also viewed schools as cultural instruments. Nationalist leaders perceived a necessity for developing icons of national culture—e.g., music, dance, performance, and art. The “rediscovery,” rehabilitation, and active celebration of traditional culture practices were seen as important in this endeavor particularly since “traditional” culture practices were often denigrated by colonial regimes. Schools, again, were seen as playing a central role in this enterprise.

Expansion of Schooling

As a consequence of the faith in the ameliorative powers of formal education, many African countries recorded significant and unparalleled (relative to the governments’ allocation to other social welfare and infrastructural commitments) expansion of expenditure to formal education. Indeed, by the mid-1980s (prior to the severe

economic downturn in most of Africa) a number of African countries were approaching the goal of universal primary education as well as recording significant gains in secondary and tertiary education.

In developing goals for schools the nascent postcolonial African regimes were generally guided by a tripartite goal: a commitment to Universal Primary Education (UPE)—with quality considerations; expansion of secondary education to meet the human resource needs of nation-state and to respond to the aspirations of citizens (but no country attempted universal secondary education); and expansion of tertiary education: at least one national university, specialized colleges—technical, allied health, teacher-training. Yet, even before the onset of economic stagnation and the implementation of structural adjustment programs in the late 1980s, both of which negatively impacted access to schooling, it had become clear that the expansion of formal education had neither paid the anticipated dividends in terms of economic development and security, political system capacity, democratization, or stability; nor had the educational expansion resulted in significant improved life chances for many African citizens. However, the growing recognition that formal education while essential was not sufficient for realizing development goals, did not significantly lessen postcolonial state commitment to education, or deter citizen demand for increased access to schooling. But, these realities resulted in the critical re-visitation of policy questions that were part of policy discussions in the immediate postindependence era. Four such questions were central to the discourse on postcolonial education policy and practice. Samoff *et al.* (1992) provide a more detailed analysis of these issues along with a comprehensive bibliography.

First is the question of the relevance of curricula. Colonial curricula following the rejection of adaptive education, was for the most part “academic” (*book learning*) aimed at producing lower-level state bureaucrats. Consequently, there was little emphasis on technical and professional skills (particularly true of higher education, where humanities were dominant). Given this tradition, in the postcolonial era there was considerable public opposition to changes in curriculum (except to Africanize history, geography, and literature). In the postcolonial era the curriculum focus continued to have a strong academic orientation. Parents and students, based on the realities of the colonial political economy, perceived “academic” education (*book learning*) with a traditional emphasis on the humanities and non-applied social and natural sciences, as essential to securing employment in the government sector. This perspective was reinforced by the realities of postcolonial economies that, restricted by the legacy and continued dominance of the colonial modes of production, were generally not diversified and as such did not provide opportunities for employment (including self-employment) outside of the “traditional” government/public sector.

By the 1980s there were, however, educational policy experts, domestically and external, who believe that a significant, if not radical, reform of the curricula was essential in order to provide young adults with the skills, attitudes, and experience necessary to be entrepreneurs and/or to diversify the economy.

A second central question focused on school fees. Most Africa countries after independence heavily subsidized education at all levels and adhered to a commitment to equal opportunity for all citizens. However, given the real costs of schooling most

postcolonial states could not hope to achieve their educational goals (including UPE) without parents/students sharing some of the actual cost of schooling. This position was pushed by the World Bank and the International Monetary Fund (IMF) beginning in the mid-1980s with the externally imposed *economic structural adjustment programs* (ESAPs). In many countries that implemented ESAP-recommended educational finance reforms there was a decline in the number of students participating in all levels of education—with no African country realizing UPE, one of the eight Millennium Challenge Goals (Birdsall *et al.*, 2005).

A third question relates to the privileging of one level of education above others. For the past two decades the World Bank and other bilaterals (based on their research) pushed for educational policies that privileged primary education—arguing that their research clearly demonstrated that the expansion of primary education had the highest rate of return, socially and personally. However, African regimes and citizens were unhappy with this policy direction. They perceived secondary and higher education as being essential for development. Moreover, African experts argued that without university-trained specialists African nation-states would be (and continue to be) dependent on exogenously produced skills and knowledge. They assert that African universities are necessary, not just to provide skilled human resources to tackle Africa's problems, but to develop endogenous and relevant approaches to these problems—approaches that are not dependent on, or restricted by, Western or global epistemologies or paradigms of knowledge production.

The fourth central question that has dominated the discourse on post-colonial educational policy and practice focuses on gender. Beginning in the 1980s there has been an increased recognition of the importance of gender in addressing all issues related to socioeconomic and political development in postcolonial Africa. Women have always played a central economic role in African societies, even though, as in *West*, women were often excluded from political positions that would give them access to power and a voice in decision-making. This systemic reality resulted in gender bias in access to all levels of education in Africa. Consequently, there is now a near universal recognition that girls and women must be given equal access to at all levels of the formal education system. In addition to being an important human rights and equity issue, social, economic, and political development and the well-being of local communities and the nation-state are dependent on the active involvement of educated women. As a result of this understanding, over the past decade almost all multilateral (World Bank, UNESCO, UNICEF) and bilateral (USAID, British Council, SEDA, etc.) funded educational projects privilege gender equity. (For a detailed analysis and comprehensive bibliography on gender schooling in Africa, see UNESCO, 2003.)

Conclusion: Globalization and African Education

The new millennium has witnessed a surge of optimism in Africa. Beginning in the 1990s Africa has undergone a significant wave of democratization—what some academic commentators have dubbed *Africa's Second Independence*. Similarly, the past decade has seen sustained economic growth rates across the continent. The creation

of the African Union in 2002 and its adoption of the realistic, if ambitious, NEPAD reinforces this sense of optimism in Africa.

Yet, in spite of these important advances, Africa in places is still plagued with internal and regional political strife, long-lasting legacies of colonialism and the cold war. On the economic front, regardless of the gains, Africa remains a continent of endemic poverty where more than two thirds of the continent's population subsists on less than \$2 a day.

It is too early to offer a comprehensive assessment of the impact of globalization on Africa. While the "flattening" of the world will undoubtedly provide some African countries with increased economic opportunities, there is a real concern that given Africa's legacy of severe economic and political underdevelopment, African states are not in a position to be competitive in the global system resulting in the further peripheralization of significant parts of Africa.

The general economic recovery of the past decade and the support from the international community has resulted in a recovery and expansion of school attendance in most African countries. Indeed, countries like Botswana, Mauritius, and South Africa are poised to realize the Millennium Challenge Goal of universal primary education by 2015. Yet these gains are dependent on external funding to support educational systems at all levels restricting the autonomy of African policymakers. The World Bank and bilateral lenders make loans and grants contingent on the implementation of policies set by experts located for the most part outside of Africa. As a consequence there is a real concern that (a) what counts as good educational practice will be increasingly exogenously determined, allowing for little local autonomy; and (b) what counts as knowledge—how it is generated, created, constructed, distributed, and used will be determined outside of Africa, with limited local input. Active engagement in the processes of knowledge construction, valuation, and distribution is based on *power* within the global community—of which Africa has little, hence Africa's voice has been muted within the global education discourse, even as it impacts approaches to Africa's development.

Formal education systems and knowledge production that foster active local engagement while capitalizing on global connections, is not as history has demonstrated sufficient to overcome the social, economic, and political structural impediments for development in Africa, but it is nonetheless essential and a *sine qua non* to its realization.

VARIETIES OF EDUCATIONAL TRANSFORMATION: THE POST-SOCIALIST STATES OF CENTRAL/SOUTHEASTERN EUROPE AND THE FORMER SOVIET UNION

Iveta Silova

The former socialist countries of Central/Southeastern Europe and the Soviet Union share many commonalities, while forming an increasingly diverse region of the world in terms of sociopolitical development. Among the most striking commonalities are the shared socialist past, as well as the sheer scale and significance of the political, economic, and social transformation since the collapse of socialism in 1989. Although all countries of the region have declared their aspiration to embrace the new values of democracy, capitalism, and market economies, the transformation process has been uneven across the region. By 2007, ten countries became new member states of the European Union (EU) – Bulgaria, the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, the Slovak Republic, and Slovenia – signaling the emergence of open, liberal societies at least partially rooted in respect for the rule of law, human rights, and economic freedom. In some countries of Southeastern Europe and the former Soviet Union, however, democratic and free-market characteristics have shared the stage with “a high degree of authoritarianism, corporatism, cronyism, and state involvement in economic life” (Freedom House, 2005). This region also includes repressive autocracies, such as Belarus, Uzbekistan, and Turkmenistan, in which there is “little or no space for opposition political groupings and independent civic activism” (Freedom House, 2005). Approximately one third of all countries have experienced armed conflicts during the transformation period, resulting in devastating effects in all spheres of life.¹

Given the diversity of these sociopolitical contexts, it is difficult to talk about the countries of Central/Southeastern Europe and the former Soviet Union as one homogeneous region. Nevertheless, these countries share several educational characteristics, as reflected in a number of educational legacies inherited from the socialist regime and a proclaimed aspiration to embrace Western educational values. Among the positive socialist legacies are solid infrastructures for educational provision and administration, fee-free education for all children, nearly universal general education enrolments, and high literacy rates. For all the concerns about its quality and comprehensiveness, the mass provision of socialist education undeniably helped to create a level of social cohesion (Heyneman, 1997, 2000), as well as very real compensatory legitimacy for the regime. During the socialist period, education also established a widely shared

public expectation for the provision of mainstream schooling at little or no cost and on a fundamentally egalitarian basis (Silova *et al.*, 2007). For all these achievements, the education systems of the post-socialist bloc were also rigidly bureaucratized, and narrowly and involuntarily vocational (Johnson, 2004). They were also institutionally fragmented, with different hierarchies of educational provision and training divided between different branch ministries, resulting in severe inefficiencies. The system was also characterized by uniform and exceptionally rigid conceptions of pedagogy and formal “didactic,” authoritarian and teacher-centered learning, overloaded and centrally mandated curricula, and insufficient attention to the quality and nature of individual student learning (Johnson, 2004; Silova, 2002). Finally, the educational systems had acute ideological weaknesses, including an imposition of socialist political indoctrination in schools.

The collapse of the socialist bloc has opened new opportunities for rethinking the aims of educational provision and revising the structure, content, and process of educational systems in the region. Despite the contextual differences, the rhetoric of educational transformation processes has been remarkably similar across the region, signaling a move from socialist education policies to more Western-oriented ones. As Birzea (1994) observed, all post-socialist countries have adopted, at least in official rhetoric, “one or another of the western ideologies” (Birzea, 1994: 55). In this context, “learning from elsewhere” has become one of the central principles of educational transformation. From the post-socialist countries of Central Europe to the post-Soviet republics of Central Asia, the catchwords of the new educational authorities have been “democratization,” “decentralization,” “liberalization,” “pluralism,” and “humanization of learning.” Educational transformation processes have generally touched all areas of education systems, triggering profound changes in education financing, governance, curriculum, textbooks, examination and assessment systems, teacher education, and infrastructure.

While attempting to transform education based on the values of Western democracies, most countries have faced a stark conceptual dichotomy between “triumphant Westernization and hopeless post-Leninist paralysis” (Hanson, 1997: 228). On the one hand, there has been a strong desire to join the Western alliance, which was accompanied by increasing international pressures for redefining national education policies in terms of the Western European values of pluralism, human rights, and tolerance, as well as cultural and linguistic diversity. On the other hand, the transformation process has been constrained by the socialist legacies as reflected in “the relatively fragile, mutable, and wavering definitions of nationhood, in the absence of a sense of unity in a common project, and in the vulnerability of the societies to find appeal in particularly militant variants of communist or nationalist ideologies” (Barkey & von Hagen, 1997: 187). In this context, educational transformation has not necessarily reflected a gradually phased replacement of “the old” socialist education policies and practices with the “new” Western ones (Silova, 2006). Instead, it involved major conceptual disputes and continuing power struggles among different groups nationally and internationally, seeking to redefine the new geopolitical educational space that the countries of Central/Southeastern Europe and the former Soviet Union have been aspiring to inhabit since the collapse of socialism.

Using the concept of educational borrowing, this chapter examines the variety of educational transformation processes across the post-socialist region and discusses how different educational systems have responded to the rapidly changing political, economic, and social environments since the collapse of socialism in 1989. This chapter explores the sources, dimensions, and directions of educational transformation processes in Central/Southeastern Europe and the former Soviet Union. By highlighting the political nature of the transformation processes and the uniqueness of the historical, political, social, and cultural contexts of each particular country, this chapter suggests that post-socialist education transformations constitute complex, dynamic processes, which inevitably result in multiple outcomes.

Theoretical Perspectives

Of post-socialist literature, the study of political, economic, and social transitions (or “transitologies”) has made one of the greatest impacts on the ways political scientists have looked at the complex web of substantive, contextual, and methodological issues surrounding the collapse of the socialist bloc (Silova & Magno, 2004). The focus of “transitions” literature has included the examination of the roles of newly emerging democratic institutions and procedures (e.g., new constitution, elections, and legislatures), the role of elites (e.g., government officials committed to democracy), and conditions necessary for consolidating newly established democracies (e.g., socio-economic, ethno-religious, cultural issues) (Przeworski, 1991; Lijphart & Waisman, 1996; Diamond *et al.*, 1997; Gerskovits, 1998). Comparative education literature has generally focused on the place which educational policies hold in nation-bound transformation processes at the intersections of their political and educational systems (Mitter, 2003). In fact, the comparative education literature examining the role of education in political transformation processes is so vast that Cowen (1996, 2000) has suggested creating a new domain of comparative education called “transitology.” He describes transitologies as complex mixtures of historical, political, economic, ideological, and sociological transformations, which reflect more or less simultaneous collapse and reconstruction of state apparatuses, social and economic stratification systems, and political visions of the future.

Similar to mainstream political science literature, most comparative education research on educational transitions has emphasized a linear direction of the transformation process, i.e. a direct movement from authoritarianism to “democracy” (Anweiler, 1992; Mitter, 1992; Birzea, 1994, 1997; McLeish, 1998; Rado, 2001). McLeish (1998), for example, provides a framework for studying processes of education transition by outlining five stages of development from an authoritarian to a democratic system, including ideological uncertainty (phase I), clarification and formulation of national policies (phases II & III), emergence of new education legislation (phase IV), and implementation of new laws and policies at the school level (phase V). Although it provides a helpful framework for thinking about transition as a phased, structured process, the model does not necessarily provide a space for the renegotiation of education policies to occur. In other words, it focuses on the *outcome* of the transition, which

is assumed to be uniformly “democratic,” while ignoring the *process* of the transition (Silova & Magno, 2004). However, the process itself may have a crucial impact on the outcome of the transition, especially when closed, undemocratic transition processes result in outcomes that bear little resemblance to true open democracies as in the cases of Belarus, Turkmenistan, and Uzbekistan.²

A growing mismatch between expectation and event in post-socialism has questioned the language of the transition itself (Silova & Magno, 2004). Some scholars have argued that the term should be discarded on the grounds that it implies evolutionary aspects of social change, an unproblematic trajectory, and a destination that is known (Watson, 2000). Others argued that the study of “transitions” has become “the second edition” of the modernization theories flawed with intellectual inconsistency and political inadequacy (Kapustin, 2001). Challenging “transitology” for its naiveté in assuming a direct movement from socialism to capitalism, democracy, or market economy, Verdery proposed that the decade of the 1990s should be viewed as a time of *transformation* in the countries that emerged from socialism. This transformation could produce “a variety of forms, some of them perhaps approximating Western capitalist market economies and many of them not” (Verdery, 1996: 16).

In comparative education, some critics of “transitology” referred to these differing outcomes of transformation processes as “retardation” (Mitter, 2003) and “mutation” (Cerych, 1997; Karpov & Lisovskaya, 2001). As Karpov and Lisovskaya describe, educational “mutations” are “spontaneous, adaptive, and historically predetermined reactions of the already existing educational institutions to the new environment” (2001: 11). Importantly, the notion of “mutations” also implies the persistence of culture- and education-specific legacies, the existence of local reinterpretation of new ideas, and the dynamic interplay between the local and the global in reshaping the new educational spaces. It is not surprising, therefore, that education transformation processes in the post-socialist bloc have taken unanticipated trajectories and led to unknown destinations.

Examining Post-Socialist Transformations Through the Lens of Educational Borrowing

The concept of educational borrowing provides a helpful framework for examining the variety of educational transformation processes in Central/Southeastern Europe and the former Soviet Union. As Schriewer and Martinez (2004: 47) point out, the transformation processes have corresponded to a “reopening of the discourse to international issues, references, and knowledge imports.” In this context, educational import, transfer, or borrowing has become one of the main strategies for education reform. Educational borrowing describes the processes involved when “policy makers in one country seek to employ ideas taken from the experience of another country” (Phillips, 2004: 54). Building on Luhmann’s (1990) theory of self-referential systems and Schriewer’s (1988) work on the use of comparison for the purpose of externalization, Steiner-Khamsi (2000) argues that education borrowing, or references to international practices, are increasingly used once the relevance of self-referentiality is questioned.

Whereas education systems usually perpetuate themselves by means of internal references (e.g. references to tradition, beliefs, and organization), these references often fail to justify the continuity of education reforms during times of rapid social, economic, and political changes. As Schriewer (1988) and Steiner-Khamsi (2000, 2004) suggest, it is precisely in those times that externalization or educational borrowing becomes an effective means to radically break with the past through transferring education models, practices, and discourses from other educational systems.

Comparative education literature on educational borrowing and lending (Steiner-Khamsi, 2004; Phillips, 2004; Schriewer, 2000) explain the complexity of the borrowing process by highlighting the instances of selective interpretation or “filtering” of international phenomena locally. For example, Schriewer and Martinez (2004) explain that externalizations to “foreign examples” or to “world situations” involve the discursive interpretation of international phenomena for issues of educational policy or ideological legitimization locally. Similarly, they argue that externalizations to “tradition” react to the need to reinterpret these traditions’ theoretical and/or normative potential in the face of urgent present-day concerns (Schriewer & Martinez, 2004: 32). Therefore, both forms of externalization – externalizations to “world situations” and to “history” – are “system-internal interpretative acts which don’t provide reliable information on how historical processes really were or what is actually going on in the world” (Luhmann, 1981: 40). As Schriewer and Martinez (2004) explain, externalizations “filter” the reception and description of an international environment according to the changing problem configurations internal to a given educational system. Their potential for selection and interpretation rearranges references to international phenomena according to a given system’s internal needs for “supplementary meaning” (Schriewer & Martinez, 2004: 32). Moreover, the need for “supplementary meaning” not only varies *between* different societies or nations, but also changes over time in the course of successive political eras *within* the same society (Schriewer & Martinez, 2004: 32).

The concept of the “supplementary meaning” points to the discursive nature of educational borrowing, which has been frequently neglected in comparative education literature. For example, most comparative research on educational borrowing has focused on examining the implementation of specific education *practices* in different historical, political, and economic settings. However, it is important to recognize that transfer can involve not only practices, but also *discourses*. As Steiner-Khamsi (2000) points out, the fact that the borrowed education program was not implemented does not mean that the transfer did not occur. Instead, what is being transferred is not a specific aspect of education reform, but rather a political discourse associated with it. It is specifically this area of comparative education research that remains understudied, yet has great potential to contribute to the study of education transformation processes in a variety of contexts. Its most significant contribution is recognizing the “causal significance of cultural and political discourses in shaping complex event sequences” (Emirbayer & Goodwin, 1994: 1436), thus establishing a link between the transfer of discourses and their relationship to greater social, economic, and political transformations. This chapter attempts to fill in this theoretical gap by taking into consideration structural, cultural, and discursive factors that provide a better understanding and a more complete explanation of educational transformations in the former socialist bloc.

These theoretical perspectives provide the background for a comparative reflection on education transformation processes in the post-socialist bloc. They highlight the complexity of educational transformations, which are driven by plural assumptions, multiple orientations, and diverse procedures. As Mitter rightfully observes, the analysis of educational transformations in Central/Southeastern Europe and the former Soviet Union should be based upon the acknowledgment of “the diversity of individual – national or regional – ‘transformations’ and on recognitions of tensions between commonalities and differences” (Mitter, 2003: 79). Given the politics of educational borrowing combined with the unique historical, political, social, and cultural contexts of each particular country, the outcomes of educational transformations may not be as clear and uniform as generally assumed. Therefore, it is necessary to move away from a linear conceptualization of the “transition” process, which is characterized by a gradual replacement of “the old” socialist policies, practices, and values with the “new” Western ones. As this chapter illustrates, post-socialist education transformations should be viewed as complex processes, which may take unanticipated trajectories and lead to multiple destinations.

Drawing on quantitative and qualitative data, this chapter discusses a variety of educational transformation processes and outcomes in three broad categories of countries. The first category includes the new European Union accession countries, including Bulgaria, the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, the Slovak Republic, and Slovenia. The second category includes countries that may aspire to enter the EU in the future. These include EU candidate countries (Croatia, the Former Yugoslav Republic (FYR) of Macedonia, and Turkey), potential candidate countries (Albania, Bosnia & Herzegovina, Montenegro, and Serbia), as well as future enlargement possibilities (Ukraine, Moldova, Russia, Kazakhstan, Armenia, Azerbaijan, and Georgia).³ Finally, the third category includes the post-Soviet republics of Central Asia (Kyrgyzstan, Tajikistan, Turkmenistan, and Uzbekistan) and Belarus – the countries that have not necessarily drawn on Western European references for reforming their educational system since independence in 1991. While many differences exist within these larger groups of countries, this categorization is used conditionally to examine the varieties of educational transformation processes in different contexts. The basis for comparison includes the type of references (e.g., internal or external references) used for initiating educational reforms, as well as the perceived compatibility between the underlying logic of external references and national education policies.

The End of Educational Transformation? Education in the New EU Accession Countries

Some scholars argued that educational transformation of the societies of the post-socialist bloc would officially end with their accession to the European Union (Birzea, in Phillips & Oancea, 2005). In this process, some of the old socialist education structures, processes, and content would be replaced with more Western-oriented ones in order to adhere to EU standards and regulations. The new EU accession countries – Bulgaria, the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, the Slovak

Republic, and Slovenia – were the first ones in the post-socialist region to successfully realign their educational system with EU standards. Of the post-socialist bloc, these countries were the first ones to join the Council of Europe (CoE) and the Bologna process.⁴ In particular, all the new accession countries joined the CoE in the beginning of the 1990s and became a part of the Bologna process in 1999, compared to the majority of the other post-socialist countries, which joined the CoE and the Bologna process only at the end of the 1990s and/or beginning of the 2000s (see Table 1).

Undoubtedly, joining the European education space has had a tremendous impact on education policies and practices in the new accession countries. While most of the EU measures do not explicitly aim at regulation of national systems and policies, they impact them more indirectly through European educational cooperation. Since the beginning of the 1990s, the new EU accession countries have participated in a

Table 1. Dynamics of participation in the European educational processes

wide range of EU-funded educational programs, which were specifically designed to help the countries prepare for accession into the EU (e.g., SOCRATES, LEONARDO da VINCI, TEMPUS, etc).⁵ The basic logic and most objectives of the EU educational initiatives – promoting international cooperation, enhancing the quality of education, encouraging social integration, and increasing employability of graduates – have generally corresponded to national development goals, forming the cornerstone of education policies in the new accession countries.

One of the strongest commonalities of educational development in these countries was their explicit use of Western European references in creating new educational spaces. Based on the analysis of education policy documents in Lithuania, Poland, and Slovenia, for example, Godon *et al.* (2004) observe that practical educational reform in these societies has oriented the schooling system to predominantly European and Western influences, which has been clearly reflected in national educational policy documents. Prominent components in these developments include a concern with the educational implications of liberal democratic principles and values (e.g., initiatives related to teaching methods, respect for diversity, and education for citizenship), with the wide-ranging educational agenda of the EU (e.g., international cooperation, quality of education, and student mobility), and with the need to temper undue state control in education (e.g., decentralization, recognition of the rights of parents and minorities). Furthermore, Godon *et al.* (2004) note that more specific concerns reflective of Western influence include initiatives relating to lifelong learning, school development, information and communication technologies (ICT), and educational management.

“Adopting the language of the new allies” has become commonplace in all the new EU accession countries (Silova, 2004). Generally, it has demonstrated that these countries are not willing to fall behind international standards in educational reform and signaled their efforts to “return to Europe” (Silova, 2002). The outcomes of these efforts have been reflected in quantitative educational indicators, especially in the area of school access and quality. For example, the report of the Commission of the European Communities, “Progress toward the Lisbon objectives in education and training” (2005), documents no significant gap between the new accession countries and the EU average in the area of education access. In the three benchmark areas which target school education (i.e., early school-leavers, upper secondary education, and low achievers), the strongest performers are in fact the new EU member states, including Poland, the Czech Republic, the Slovak Republic, Slovenia, as well as Latvia in the area of reducing the share of low achievers. For example, an average ratio of early school-leavers in the new EU member states was 7.5% compared to an average EU ratio of 15.9%. Similarly, the new member states have particularly high completion rates in upper secondary education, with the Czech Republic and the Slovak Republic over 90%, compared to the EU average of 76.4%. The only area where the new accession countries are still lagging behind is life-long learning, with seven out of eight countries in the study performing below the EU average.

In the area of educational quality, the new accession countries achieve scores which compare favorably with international averages in mathematics, science, and reading. For example, the results of the 2003 Trends in International Mathematics and Science Study (TIMSS)⁶ showed that the six new accession countries participating in the

study⁷ scored above the international average. However, the results of the Programme for International Student Assessment (PISA)⁸ showed a less favorable picture. On a reading scale, the Czech Republic, Hungary, the Slovak Republic, and Latvia scored below the OECD average, while Poland scored higher than the OECD average. On a mathematics scale, all countries scored below the OECD average except for the Czech Republic and the Slovak Republic (OECD, 2004). While the data on student learning achievement shows that most of the new accession countries provide comparatively high-quality education, it also suggests that learning achievement tends to vary within countries, with students from rural areas and disadvantaged socioeconomic backgrounds becoming increasingly more vulnerable (UNESCO, 2005; IEA, 2004; OECD, 2004).

Reconciling European Values with Specific Historical, Political, and Cultural Contexts

Although the new accession countries have made major progress toward EU educational standards since the beginning of the 1990s, EU accession itself has not meant the end of educational transformation processes. In fact, most of the accession countries are still struggling to reconcile some of the EU values with their own specific historical, political, cultural, and educational contexts. One of the distinctive features of these ongoing transformation processes is the degree to which the new educational rhetoric has been embedded in national policies and practices. In some countries (e.g., the Czech Republic, Hungary, the Slovak Republic) new education policies were adopted, yet fell short of practical implementation. For example, some Roma in the Czech Republic saw the EU as “a promised land, where the problems of poverty, unemployment, and inferior education would be wiped out” (Husova & Puncheva, 2005). Two years after accession to the EU, however, life for Czech Roma has hardly changed. As Husova and Puncheva (2005) explain, the country boasts numerous government programs and strategies to help Roma on paper, but does nothing to implement its strategy on Romani integration. According to the Czech government’s own estimates, “around 75% of Romani children are transferred to or directly enrolled in remedial special schools” (quoted in PILI, 2005). Similarly, segregation of Romani children is still prevalent in the other new EU accession countries, especially in Hungary and the Slovak Republic (PILI, 2005). In these countries, various patterns of educational segregation continue to exist, including the placement of Roma into special schools for the mentally handicapped, the separation of Roma in Roma-only classes within mainstream schools, and the maintaining of Romani ghetto schools located in the Romani ghettos or formed as a result of the withdrawal of non-Roma from Roma-majority schools. While the EU accession process was instrumental in placing the issue of Roma equity on the political agenda and improving Roma protection standards in the new accession countries (e.g., most governments have acceded to key international standards and many have carried out legislative reforms and announced programs to combat discrimination), it has not in practice ensured the real enforcement of minority protection laws and policies (EUMAP, 2002).

In other countries (e.g., the Baltic states of Latvia and Estonia), new educational policies were adopted and enacted, but became the subject of broad reinterpretation by local politicians and education stakeholders during the implementation process (Silova, 2006). For example, Latvia inherited a dual system of education, which segregated students along ethnolinguistic lines (i.e., schools for Russian-speaking and Latvian-speaking students). Whereas the structure of the school system did not substantially change since the collapse of the Soviet Union, education reform discourse about separate schools for Russian and Latvian students underwent a great transformation. Russian language schools moved from being associated with “Soviet/Russian state instruments” and “nests of Soviet occupants” in the early 1990s to “symbols of multiculturalism and pluralism” by the end of the decade. This change occurred under the political contingencies of the mid-1990s surrounding tolerance, language minority protection rights (Russian), and multiculturalism. These contingencies had been imposed on the Latvian government by international organizations (the Organisation for Security and Cooperation in Europe, the Council of Europe, the United Nations Development Programme), and they had a gatekeeping function. As long as the government was not willing to subscribe, at least rhetorically, to these common European goals, the country was not permitted entry to the European Union. The government insisted that the dual-school system, supported by Russian and ethnic Latvian speakers for entirely different reasons, was in concert with the conditions set by international organizations. Rather than presenting the system as legacy from an oppressive Soviet past, the government reframed it as a signpost for a multicultural European future. The metamorphosis of the dual system in Latvia stands as a case for discursive policy borrowing – merely the language, but not the reform of multiculturalism, was adopted.

These quantitative and qualitative data illustrate that the EU accession process has triggered major educational changes (either structural or rhetorical) in the new accession countries, but the accession itself has not meant the end of educational transformations. As Birzea (quoted in Phillips & Oancea, 2005) notes, the post-socialist transformation may have officially ended with the accession to the European Union (EU), i.e. meeting the three Copenhagen criteria in the area of education.⁹ Following the accession to the European Union, however, these countries continue to transform their educational systems, trying to reconcile some of the European values with their specific historical, political, cultural, and socioeconomic contexts. While driven by the same philosophical values, the transformation processes occur at a different pace and result in different outcomes. Furthermore, the EU accession has brought new challenges in educational development of the new accession countries. Not only must the new member states cope with their own transformation processes, but they have also become part of another transformation process – shared with the rest of the European Union – toward knowledge-based societies. As Halasz (quoted in Phillips & Oancea, 2005) points out, the EU is in fact a “moving target” for the accession and candidate countries. Given that “the point of arrival” may itself not remain constant, the countries could be in a “perpetual transformation” (Birzea, 1994: 8). Taking this into consideration, it would be more appropriate to talk about *continuous transformations* when examining education transformation processes in the new EU accession countries.

Catching Up and Falling Behind: Education Transformation in the Post-Socialist Countries Aspiring to Join the European Union

In addition to the eight former socialist countries that joined the EU in 2004 and two additional countries that joined the EU in 2007, a number of other countries expressed their interest in joining the European education space. These countries include EU candidate countries (Croatia and the Former Yugoslav Republic of Macedonia), potential candidate countries (Albania, Bosnia & Herzegovina, Montenegro, and Serbia), as well as future enlargement possibilities in Eastern Europe and South Caucasus (e.g., Ukraine, Moldova, Russia, Kazakhstan, Armenia, Azerbaijan, and Georgia). During the 1990s, these countries initiated fundamental reforms of their educational systems. As Ammermüller *et al.* (2003) summarize, the administration of schooling was decentralized, national schools were established to foster national culture and languages, and the heterogeneity of schools increased, changing from a system of only one basic school to more specialized institutions like the gymnasium or technical and vocational schools, as well as private schools. In most of the post-conflict societies (e.g., the Balkans and the Caucasus, which experienced armed conflicts during the transformation period), education reforms also emphasized the respect for human rights and paid special attention to minority education (OECD, 2001a, b). Across the region, education reforms have involved policy development, teacher training, curriculum development, as well as financial restructuring. By the mid-1990s, most of the countries have joined the Council of Europe and, by the mid-2000s, all the countries (with the exception of Kazakhstan) have joined the Bologna process. As Cerych (1997) points out, the many educational changes that have occurred cannot be separated from EU programs such as Tempus (higher education) and Phare (vocational education), as well as from the flow of information and exchanges originating in meetings, seminars, and publications of the Council of Europe.

Having articulated their aspiration to “catch up” with Europe, the majority of the countries aspiring to join the EU have struggled with the slow pace of reforms, which have been seriously complicated and delayed by the legacies of the socialist past. In some countries, these legacies have led to violent armed conflicts (e.g., the Caucasus, the Balkans, etc). In other countries, the socialist legacies have manifested themselves at different levels, including the more straightforward infrastructural legacies, the administrative–bureaucratic legacy, and the more elusive political and cultural continuities (Barkey & von Hagen, 1997). In particular, post-conflict societies have had to deal with economic recession, unemployment, destruction of school buildings, demoralization of teaching staff, psychological trauma of children, and many other problems which have slowed their education reform efforts (OECD, 2001a, b). Most of the countries have dealt with major economic recession during the 1990s, with the real expenditure of education falling one third in Russia and three quarters or more in Azerbaijan and Georgia (Micklewright, 2000; see also Table 2). The fall in real public spending on education has generally meant lower teacher wages and/or wages paid in arrears (e.g., a major problem in the education sector in Russia and Kazakhstan), insufficient

funding for school repairs and maintenance leading schools to close on occasion in winter in a number of countries (e.g., Armenia, Georgia, and Moldova), and less social support through schools (e.g., Kazakhstan and Georgia). Furthermore, all countries have dealt with increasing levels of corruption in all spheres (including the education sphere), with most of the countries scoring below 3.0 out of 10.0 on the Corruption Perception Index (with ten being the least corrupt and zero being highly corrupt).¹⁰

Undoubtedly, these legacies have impeded educational transformation processes in various ways, causing most of the countries to fall behind in their efforts to create or re-create European education space. While overall school retention in the region has remained almost universal, in some countries a significant proportion of school-leavers no longer achieve the minimum mastery levels defined by their own national governments. For example, results of the Progress in International Reading Literacy Study (PIRLS)¹¹ in 2001 indicated that large numbers of fourth graders (9- to 10-year-olds) in the Former Yugoslav Republic of Macedonia had limited reading skills, with more than 40% scoring in the bottom quartile on the international reading literacy scale. In other countries, the proportion of low achievers ranged from 21% in the Republic of Moldova to 8% in the Russian Federation (IEA, 2003). Other confirmation comes from the PISA study (2000–2002), which covered 35 high- and middle-income countries. It showed that while 18% of 15-year-old students in the OECD countries performed at or below the lowest of five proficiency levels for reading literacy, this category accounted for 71% in Albania and 63% in the FYR of Macedonia. Similarly, the TIMSS results (IEA, 2004) showed that while all new accession countries participating in the study scored above the international average, the majority of the countries aspiring to join the EU scored lower than the international average in mathematics and science. In particular, eight-graders in Moldova and the FYR of Macedonia scored lower than the international average in mathematics and eighth graders in Moldova, Serbia, Armenia, and the FYR of Macedonia scored lower than the international average in science (see Table 3).

Western Models, Local Realities, and Educational “Mutations”

Reflecting on the education transformation process in the former socialist bloc, Johnson noted that both post-socialist countries and their Western allies were more often guided by idealized Western models than by an accurate sense of their needs and capacities (1996: 119). As a result, many of the reform initiatives have “mutated,” resulting in different outcomes than originally expected. Based on an examination of the equality of educational opportunities in the countries undergoing post-socialist transformation processes, Micklewright says that “the picture is clouded by the positive aspects of greater variation in educational provision,” as reflected in such commonly used “buzzwords” as “more choice and less homogeneity in supply” (2000: 23). However, the evidence from many countries points to the emergence of more unequal educational systems in a negative sense (Micklewright, 2000: 23). This is the conclusion, for example, of the OECD’s review of educational

policy in the largest country undergoing education transformation, Russia. Having listed a range of concerns about preferential access to better educational opportunities, the report states:

Under the banner of “increased choice,” all these concerns point paradoxically to diminished educational opportunities for many children, especially those who are rural, less affluent, or less well-connected – regardless of their individual merit. . . . As Russian society becomes increasingly stratified in terms of wealth, Russian education is increasingly stratified in terms of opportunity. (OECD, 1998: 79, 82)

The declarative commitment to equity and access may no longer be the case in other former socialist countries as well. In the present climate of economic recession, secondary school elitism (private schools and elite state schools) is growing, and is reinforced by the ability to pay (Zajda, 2003). This is reflected in a recent study on private tutoring in the nine countries of the post-socialist bloc,¹² where the majority of the respondents believed that private tutoring was essential for receiving high-quality education (Silova *et al.*, 2006). This has serious equity implications, as students from privileged and wealthy family backgrounds are more likely to have access to more and/or better-quality education. The data reveal that students who perceive their family welfare as below the national average take private tutoring less frequently than students who estimate their family welfare as average or above average. In the total sample, private tutoring lessons were used by 41% of all students who estimated their family welfare as above the national average, compared to approximately 28% of students who indicated that their family welfare was below the national average. Among non-private-tutoring users, almost a half (46%) estimated their family welfare as below the national average, further confirming the limited access of private tutoring to families from lower socioeconomic groups (Silova *et al.*, 2006).

Not only does the inability to pay deprive many children of quality education, but it can also limit their access to education. According to Tomaševski (2005), education has become “legally free, but really unfree” in all the countries undergoing post-socialist transformations.¹³ The increasing incidence of direct charges, even in compulsory primary education, victimizes the children of the poor who cannot afford to pay for books, materials, private tutoring, transport, meals, or even for supplements to teacher salaries, or school building maintenance. A recent survey of school nonattendance and dropout in the six countries of the former socialist bloc confirms that poverty is the main reason for school dropout (Open Society Institute, 2007).¹⁴ The survey cites the inability to pay for school supplies and other direct costs charged to families as a contributing factor to dropout. For example, the Kazakhstan survey (Open Society Institute, 2007) confirms that the majority of families with children who dropped out of school (63.8%) have incomes below 25,000 tenge (€150) per month, and just over 50% of these families have three or more children. In several countries (e.g., Albania, Moldova, Kazakhstan), many children of school age find it necessary to earn money to help support their families, and although there are both international conventions and national laws regulating child labor, certain sectors of the economy depend heavily

on it (e.g., agriculture). For example, a UNICEF (2000) study reports that 31.7% of children in Albania between the ages of 5 and 14 were working; in the city of Dürres alone, 60% of boys over the age of 10 were working. Similarly, absenteeism among poor children in Moldova has risen as children drop out to join the labor force (Open Society Institute, 2007; UNICEF, 2001). As such, compulsory schooling laws no longer ensure that children of the specified age range are actually in school. There is a wide gap between what the laws (and international conventions on human and child rights) require, and the day-to-day reality of children's lives (Tomaševski, 2005).

To summarize, the post-socialist countries aspiring to join the EU have been undergoing complex education transformation processes aimed at repositioning themselves within the European education space. While the EU has become a particularly influential context for educational development in these countries, it has also highlighted some of the tensions in reconciling “Western” ideas with local realities. European Union integration efforts have been generally welcomed (e.g., as reflected in the “borrowing” of EU education rhetoric and participation in various EU programs and processes), but they have also released tensions between national identities and the European dimension on the one hand, and tensions between the socialist legacies of a centralized plan economy and the current drive toward a market economy, on the other (Tjeldvoll, 2006). In the midst of this situation of conflicting values and interests, the educational systems have been struggling to balance their two main functions – the guarantee of free compulsory

education for all children and the provision of quality education. In this process, Western educational ideas have often “mutated” as they encountered local spaces, causing the educational systems to become increasingly inequitable in terms of income level, socio-economic status, geographical location (urban/rural), ethnicity, and gender.

Lost in Transformation: Education in Post-Soviet Central Asia

While most of the Central/Southeastern European countries were enthusiastic in their efforts to overcome the socialist past and join the European education space, most of the Central Asian republics have actually insisted on keeping many of the Soviet educational traditions and practices, while creating their own unique models of educational development. In Uzbekistan, Turkmenistan, and Tajikistan, education reform efforts have been primarily based on internal references to Soviet educational practices. In fact, Soviet education is more explicitly described as the “good old” system which can offer hope toward overcoming the current crisis (Belkanov, 2000: 86). Furthermore, many policymakers have become openly hostile to any Western influences, especially in the sphere of education. In an interview broadcast on Uzbekistan’s TV, for example, President Karimov complained about outsiders’ “increasing attempts to come to our country and lecture us “just as” big brother Moscow” used to do before the collapse of the Soviet Union (RFE/RL, 2003).

These Central Asian republics have probably faced the most difficult problems of transformation, with some countries experiencing major setbacks in all areas of education provision. In some countries, the situation has become so challenging that one of the education stakeholders in Turkmenistan referred to “education reform” as “education deform” (personal communication, June 4, 2005). During the 1990s, the Central Asian republics entered dramatic economic declines, resulting from the loss of traditional economic networks and the end of budget subsidies and transfers from Moscow. Given the overall decline in national incomes, investments in the educational sector have remained chronically low compared to pre-independence levels (Silova *et al.*, 2007). In the 2002/2003 academic year, for example, Tajikistan contributed 2.6% of GDP for education expenditure compared to 3.8% in Kyrgyzstan, 5.7% in Turkmenistan, and an average of 4–6% in OECD countries (UNICEF Transmonee, 2005).

Predictably, this sharp decline in educational finance led to the serious physical deterioration of school facilities across the region. In all countries, schools have deteriorated due to the insufficient maintenance of property (i.e., practically no resources were allocated for school building maintenance over the past 20 years) and intensive use or overuse of school and university facilities (i.e., using schools in multiple shifts because of the growing school-age population). In addition, Tajikistan has suffered from property damage inflicted during the civil war of the early 1990s, which left 20% of all schools destroyed, looted, or severely damaged (Silova *et al.*, 2007).

Marked declines in school enrollment have become common across the region. Preschool enrollment has declined catastrophically over the past decade, threatening the health, nutrition, and school-preparedness of children who no longer have access to these services. In 1999, the overall preschool enrollment rate in post-Soviet Central Asia was

14%, in contrast to 73% in post-socialist Central Europe. Similarly, in basic education (grades 1–9), enrollment rates appear to be dropping across the region, most dramatically in Tajikistan, which saw a drop in over half of the enrollment rate for ages 15–18, with a decline of almost 20% in Uzbekistan (UNICEF Transmonee, 2005). Compared with the rest of the former Soviet Union and Eastern and Central Europe, the Central Asian republics have some of the lowest student enrollment rates in secondary, vocational, and technical education, and are only slightly ahead of the impoverished areas of the southern Caucasus. In Uzbekistan and Tajikistan, female students have been most seriously affected. In Uzbekistan, for example, more than 25% of girls do not continue education after they reach the working age. Of all higher education students there, women constitute only 37.8% (Ministry of Macroeconomics and Statistics & State Department of Statistics of Uzbekistan, 2002). In Tajikistan, women constitute approximately 25% of all higher education students, uncovering a growing differential between young men and women (State Statistical Agency of the Republic of Tajikistan, 1998).

Undoubtedly, the quality of education has suffered, with many students failing to reach the minimum educational standards. For example, a recent Monitoring of Learning Achievement (MLA) study in Kyrgyzstan (Ministry of Education, Science and Youth Policy of the Kyrgyz Republic, 2005; Ministry of Public Education of the Republic of Tajikistan, 2002) showed that only 44.2% of all surveyed fourth graders passed the minimum literacy test and 58.5% passed the mathematics tests. In Tajikistan, the same study showed that an overwhelming number of fourth-grade students failed basic literacy test (63%) and mathematics test (50%). In both Kyrgyzstan and Tajikistan, students from urban areas scored the highest, while students from the remote rural areas scored the lowest. As the MLA reports explained, learning achievement has been negatively affected by such factors as insufficient teacher qualifications, lack of appropriate textbooks and teaching/learning materials, inappropriate teaching/learning methods, and a lack of education support at home. In Turkmenistan and Uzbekistan, the education system is further undermined by a high level of political control. In Uzbekistan, President Karimov's numerous books are part of the higher education curriculum and must be mastered to enter university and pass graduation examinations. In Turkmenistan, the cult of personality of President Niyazov is imposed in schools via the compulsory and almost exclusive study of his book *Rukhnama*.

It is in this environment of collapsing educational structures and increasing political control that “Western” educational ideas were introduced in Central Asia through international financial assistance in the 1990s. Major international organizations – such as the Asian Development Bank, the World Bank, Council of Europe, UNICEF, UNESCO, Agha Khan Foundation, and the Soros Foundations network – “moved to support development, promote democracy and buttress stability in Central Asia” (Open Society Institute, 2002). Following international assistance money, “traveling policies” have spread quickly across post-Soviet Central Asia. Notwithstanding the diversity of local contexts and the variety of international agencies funding education reform initiatives, the proposed recommendations for saving “the generation at risk” have emphasized such commonly articulated solutions as decentralization, privatization, increasing student/teacher ratios, improving in-service teacher training, curriculum reform, and others (Silova, 2005). In just over a decade, Central Asian education discourses have become practically identical to those of other post-socialist countries.¹⁵

“Traveling Policies,” Soviet Legacies, and Pre-Soviet Traditions

While Central Asian education reform rhetoric has echoed education development trends in the rest of the post-socialist bloc, education practices have not substantially changed. In Tajikistan, for example, international pressures to address deteriorating gender equity in education led to the introduction of gender quotas in higher education at end of the 1990s.¹⁶ However, policy implementation resulted in mixed outcomes. Already in the first year of the implementation of the State Program, for example, it was observed that the number of female students in higher education institutions was not increasing sufficiently for several reasons (Silova & Magno, 2004). First, the amount of financial assistance provided to young women was so meager that it could hardly cover expenses necessary to continue studies in higher education institutions (e.g., purchase textbooks, pay for accommodation and food, etc.). Second, young women from rural areas were continuously discouraged from entering higher education because of increasingly deteriorating and unsafe conditions in dormitories. Furthermore, as soon as international pressure decreased (i.e., following the adoption of gender quota policies for higher education), there emerged new interpretations of how gender quotas should be administered. For example, female students received quotas for studying less popular and usually lower-paid professions traditionally perceived as “feminine” (e.g., nurses and teachers), while few quotas were given to women for studying more popular, higher-paid professions (e.g., law, economic, business, etc.). In other words, borrowing of the Western concepts of “gender equity” maintained their original meaning only at the “policy talk” level. At the implementation stage, however, they were skillfully used to promote increasingly patriarchal values prevalent in society. As such, educational borrowing has largely resulted in the transfer of international norms of gender equity and democratization, while their performance and implementation has primarily depended on historical legacies and local political factors (Silova, 2005).

While Central Asian education discourse has become increasingly similar to that of the rest of the world, education practice has not substantially changed. “Traveling policies” have increasingly clashed with a strong desire of education policymakers in the region to maintain Soviet education legacies and, in some cases, revive pre-Soviet traditions. As a result, “traveling policies” have not been necessarily implemented. Instead, communities at national, regional, or local levels have begun to interact with and negotiate these “traveling policies” and, in some cases, contest and resist them. In this way, educational transformation processes in most Central Asian republics have taken different trajectories, often completely diverging from the officially articulated education solutions. Behind the rhetoric of “democratization,” “internationalization,” and “equality,” some countries (especially Turkmenistan and Uzbekistan) have used education as tools of political indoctrination and repression.

Varieties of Educational Transformations

One of the unique features of post-socialist transformation processes is the degree of commonalities and differences across the region. Among the most striking commonalities is the “post-socialist education reform package” that was transferred to the

countries in Southeast/Central Europe and the former Soviet Union after the collapse of post-socialist bloc (Silova & Steiner-Khamsi, 2008). From the new EU accession countries to the post-Soviet Central Asian republics, educational policymakers have used remarkably similar education reform rhetoric, consisting of the following “package:” extension of the curriculum to 11 or 12 years of schooling, introduction of new subjects (e.g., English and computer literacy), student-centered learning, electives in upper-secondary schools, introduction of standards and/or outcomes-based education, decentralization of educational finance and governance, reorganization of schools (“rationalization” of staff and structures), privatization of higher education, standardization of student assessment, liberalization of textbook publishing, and the establishment of education management and information systems. This “post-socialist reform package” was supplemented with a few country-specific reforms, such as an emphasis on post-conflict education in war-torn countries, or on gender and education for Muslim countries. Arguably, what was stressed in the reform package is as interesting as what was omitted. In each case there was limited support from international agencies and financial institutions for teacher training, rural education, or inclusive education targeting students with special needs (Steiner-Khamsi & Stolpe, 2006:189).

The commonality of educational reforms in these post-socialist countries can be explained by several factors. The educational systems in these countries were until 1990, with a few exceptions, almost identical, reflecting Soviet influence in the region. Moreover, these countries not only experienced these structural reform policies during the same period (early and mid-1990s), but these policies were administered by the same international donors (Council of Europe, World Bank, USAID, and UN organizations). For the new accession countries and the countries aspiring to join the EU, the European educational assistance was, perhaps, the most influential in affecting education reform rhetoric. This is particularly so in relation to such concepts as “globalization,” “knowledge society,” “accountability,” and “democratization” (Lawn & Lingard, 2002: 299). For the Central Asian countries, most reform pressure came from international financial institutions, especially the World Bank and the Asian Development Bank. Across the post-socialist bloc, “traveling policies” (Lindblad & Popkewitz, 2004) had the same objective – the transformation of the previous Soviet system of education into an international model of education – designed by international financial institutions and organizations. This model was imposed in a few cases, but for the most part, it was voluntarily borrowed for fear of “falling behind” internationally (Steiner-Khamsi & Stolpe, 2006: 189).

While some scholars would argue that the apparent commonalities of educational reforms in the countries of the post-socialist bloc reflect the convergence of educational systems toward the same “world standards” with regard to the structure, organization, and content of education (Meyer & Ramirez, 2000: 120), this chapter takes a stance that is opposed to neoinstitutionalism or world culture theory. Undoubtedly, certain educational concepts or discourses go global, but they may play out differently in different political, economic, and cultural contexts (Anderson-Levitt, 2003) and they may resonate for different reasons in different educational systems (Schriewer & Martinez, 2004). As this chapter reveals, there is a convergence of educational reforms

in the countries of the post-socialist bloc, but only at the level of “buzzwords” and “brand names,” that is, in the *language* of educational reforms. Once a discourse is transplanted from one context to another, it changes meaning. Given the political and economic dimensions of education borrowing (Steiner-Khamsi & Stolpe, 2006), the transfer of global concepts can be used by local agency as a mechanism for reaching its own needs such as legitimizing contested educational reforms domestically or “signaling” certain reform movements internationally (Silova, 2002). An inquiry into how local forces encounter global reforms and what makes them adopt, resist, or undermine external pressure on domestic educational reforms is a terrain that deserves far more exploration.

Whether globalization in education is real or imagined, it is uncontested that it is the “semantics of globalization” (Schriewer, 2000: 300) that has been increasingly enlisted to accelerate educational reform in the countries of the post-socialist bloc. Despite rhetorical commonalities, however, post-socialist educational transformation processes have not been homogeneous in their trajectories, substance, and pace. In Bulgaria, the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, the Slovak Republic, and Slovenia, the EU accession process has triggered major educational changes (either structural or rhetorical), but the accession itself has meant neither the absolute uniformity of educational systems nor the end of educational transformations. All the new EU accession countries continue educational transformation processes, attempting to reconcile some of the EU values with their historical legacies. As Ivan Wilhelm, the rector of Charles University in Prague, noted, “European dimension does not have to mean uniformity. The national traditions produced by the historical developments of the last ten centuries are too valuable and important to the definition of national identity to be disregarded” (interviewed on August 23, 2004). Furthermore, the new accession countries have become a part of another transformation process – shared with the rest of the European Union – toward knowledge-based societies.

Similarly, EU institutions were instrumental in influencing educational reform in countries aspiring to join the European Union. While educational transformations in these countries have had a common destination (e.g., joining the European education space), the pace of educational reforms have been much slower, with most countries being “weighted down by totalitarian experiences and structures whose residual effects will be felt for a long time to come” (Birzea, 1994: 10). Furthermore, educational reforms borrowed from the “West” have often mutated as they clashed with socialist legacies during the implementation stage. As a result, educational systems in many countries have become increasingly inequitable in terms of socioeconomic class, geographic location, and gender.

Finally, educational transformations in the Central Asian republics have been based not only on “external references,” but also on internal references to Soviet and pre-Soviet educational practices. On the one hand, international financial institutions have introduced a plethora of “Western” educational solutions to the emerging “crisis” in the educational systems of the Central Asian republics. On the other hand, Central Asian education policymakers have attempted to maintain some of the Soviet educational traditions and/or revive pre-Soviet educational practices. Given the incompatibility between “global” ideas and local practices, educational transformation processes

in most Central Asian republics have taken different trajectories, often completely diverging from the officially articulated educational goals of “democratization,” “internationalization,” and “equality.” Behind the internationally acceptable discursive façade, some countries (especially Turkmenistan and Uzbekistan) have used educational transformation to boost political indoctrination and repression in schools.

A comparative reflection on educational development in the countries of the former socialist bloc highlights a variety of educational transformations, which may take different forms and result in a multiplicity of outcomes. Not only are there major variations in the pace, trajectories, and outcomes of educational transformation processes between the larger groups of countries (i.e., the new EU accession countries, countries aspiring to join the EU, and Central Asian republics), but there are significant variations within the groups themselves. Clearly, the “teleology of transition” (Verdery, 1996: 227), which has once again mapped out a schematic course of development for the states of the former socialist bloc, has failed to explain the complexity of educational transformations. As Steiner-Khamsi and Stolpe note, the pattern of deterministic positioning in the course of this history was all too familiar, and something else also created a sense of *déjà vu*: “After a few years of progress along the new course of ‘transition,’ more or less according to the prescriptions imposed by international financial institutions, the promised ideal – this time defined as a prospering market-oriented democracy – has once again failed to materialize” in many post-socialist countries (Steiner-Khamsi & Stolpe, 2006: 64). Clearly, it is necessary to move away from a linear conceptualization of the “transition” process, which is characterized by a gradual replacement of “the old” socialist policies, practices, and values with the “new” Western ones. Instead, it is important to account for the complexity of the post-socialist transformation processes and examine how patterns of thought move through different layers of the global and local systems and are transmuted when encountering local spaces. Under which conditions educational borrowing hybridizes, replaces, or reinforces existing practices is a key issue for understanding educational transformation processes, and should therefore be placed at the center of comparative education research.

Notes

1. Following the collapse of the socialist bloc, armed conflicts broke out in the Caucasus (including Armenia and Azerbaijan in 1988–1994 and Georgia in 1990–1994), in Central Asia (including in the Ferghana Valley in 1989–1991 and Tajikistan in 1992–1993), the former Soviet republics (including the northern Caucasus of the Russian Federation in 1992–2001 and Moldova in 1992), and the former Yugoslav Republic (including former Yugoslavia in 1991–1995, Federal Republic of Yugoslavia in 1997–1999, and FYR Macedonia in 2001).
2. Several post-Soviet governments, such as those in Belarus, Turkmenistan, and Uzbekistan, proclaim to be democratic while maintaining relatively totalitarian and sometimes repressive regimes.
3. All these countries are members of the Council of Europe (CoE), with the exception of Kazakhstan, which applied for observer status at the Parliament Assembly in 1999. The official response of Parliament Assembly of the Council of Europe (PACE) was that Kazakhstan could apply for full membership, because it is partially located in Europe, but that it would not be granted any status whatsoever at CoE until its democracy and human rights records improved.

4. The purpose of the Bologna process is to create the European higher education area by harmonizing academic degree standards and quality assurance standards throughout Europe for each faculty and its development. It is named after the place it was proposed, the University of Bologna, with the signing in 1999 of the Bologna Declaration by ministers of education from 29 European countries in the Italian city of Bologna. This was opened up to other countries, and further governmental meetings have been held in Prague (2001), Berlin (2003), and Bergen (2005).
5. For example, the SOCRATES program aims to promote the European dimension and to improve the quality of education at all levels of education by encouraging cooperation between participating countries through promoting lifelong learning, encouraging access to education for all, and acquiring qualifications and recognized skills. LEONARDO da VINCI is the action program for implementing the EU vocational training policy. Finally, the TEMPUS program assists the countries of the former socialist bloc in the restructuring of higher education systems in order to adapt them to the requirements of a market economy. In addition, all the new accession countries joined the Bologna process in 1999, thus expressing their commitment to coordinate national education policies in order to adopt a system of comparable degrees; employ a system of credit units; and promote mobility, cooperation in quality assurance, and a European dimension in higher education.
6. The Trends in International Mathematics and Science Study (TIMSS) was developed by the International Association for the Evaluation of Educational Achievement (IEA) to measure trends in students' mathematics and science achievement. Offered in 1995, 1999, 2003 and 2007, TIMSS provides participating countries with an opportunity to measure students' progress in mathematics and science achievement on a regular four-year cycle.
7. In 2003, six new EU accession countries participated in the international TIMSS study, namely Estonia, Hungary, Latvia, Lithuania, the Slovak Republic, and Slovenia.
8. The Programme for International Student Assessment (PISA) is a project of the Organisation for Economic Co-operation and Development (OECD) designed to provide policy-oriented international indicators of the skills and knowledge of 15-year-old students in three literacy domains: Reading, Mathematics, and Science. PISA aims to assess to what degree students approaching the end of their compulsory education have acquired some of the knowledge and skills that are essential for full participation in society.
9. In June 1993, the Copenhagen European Council recognised the right of the countries of Central and Eastern Europe to join the European Union when they have fulfilled three criteria: (1) political (stable and democratic institutions, the rule of law, human rights, and respect for minorities); (2) economic (a functioning market economy); and (3) incorporation of the Community *acquis* (adherence to the various political, economic, and monetary aims of the European Union).
10. A score of 5.0 is the number Transparency International considers the borderline figure distinguishing countries that do and do not have a serious corruption problem. The Corruption Perception Index scores are below 3.0 in the following countries: Armenia (2.9), Bosnia & Herzegovina (2.9), Moldova (2.9), Serbia and Montenegro (2.8), Macedonia (2.7), Kazakhstan (2.6), Ukraine (2.6), Albania (2.4), Russia (2.4), Georgia (2.3), and Azerbaijan (2.2).
11. PIRLS is part of a five-year cycle of assessments that measures trends in children's reading literacy achievement and policy and practices related to literacy. PIRLS provides trends and international comparisons on fourth-graders' reading achievement, students' competencies in relation to goals and standards for reading education, the impact of the home environment and how parents can foster reading literacy, the organization, time, and materials for learning to read in schools, as well as curriculum and classroom approaches to reading instruction.
12. The countries involved in the study included Azerbaijan, Bosnia & Herzegovina, Croatia, Georgia, Lithuania, Mongolia, Poland, Slovakia, and Ukraine.
13. All the countries aspiring to join the European Union in the future provide legal guarantee of free education, but they all levy additional charges. For more information, see <http://www.right-to-education.org/>
14. The countries involved in the study included Albania, Kazakhstan, Latvia, Mongolia, Slovakia, and Tajikistan.
15. See Silova (2005) for a more detailed discussion of "traveling policies" in Central Asia.
16. See the National Plan of Action to Improve the Situation of Women in the Republic of Tajikistan.

THE EUROPEAN UNION AND EDUCATION IN SPAIN

José Luis García Garrido

The title at the head of this article could give rise to many diverse interpretations. One of these is the study of to what degree the Spanish education system relates to the education policy which the European Economic Community first and the European Union later have drawn up since their creation. Without doubting the interest of this line of exploration, I prefer one that seems to me more realistic and revealing in the present circumstances. In my opinion, the European Union, in educational matters, is none other than the sum of all its parts. In other words, I am not convinced that its member states have given the Union the possibility of implementing a real community education policy or that they are going to do so in the near future. The States which compose the European Union jealously keep exclusive control over their respective education systems and it seems they wish to continue that way while accepting, not without resistance, that Brussels may collaborate in establishing certain common lines of action.

The aim of the following pages is, therefore, to place the present Spanish education system in its natural framework which is without doubt that of the European Union. However, I will consider more the different States that compose it and their respective policies rather than the education policy of the Union itself, a policy which is, I feel, doubtful. I would like to examine, ultimately, in what sense the Spanish education system is homologous to that of the principle States of the European Union. An ambitious aim, without doubt, which contrasts the lack of space available and the complexity of the topic. Given these limitations, I am forced to choose a few points that I consider of major importance regarding the presence of the Spanish education system within the European Union. In particular, I will refer only to three. The first, of a historical nature, hopes to illustrate many of the present-day differences. The second point refers to what many Spanish academics and I consider the macro-problem facing the Spanish education system: its own nature as an education system. Finally, I will try to list, briefly, some of the main deficiencies which affect the Spanish education system with the European framework.

The reader might be surprised by the strongly critical, perhaps autocritical, character of the following pages. As will be noted, it seems as if I have tried to show only the negative aspects of the education system which I myself serve and have served for many years, thus succumbing to the typically Spanish tendency that I will analyse later: a plaintive and even pessimistic tone in my reflections. This does not comply with my usual vision as the reader can confirm in my other writings.¹

Europeanism and Isolationism in the Spanish Education Policy: An Old Topic

The large historiographic material produced in Spain in the last decades referring to education in its diverse aspects expresses tacitly or openly that from the Enlightenment onwards, Spain did not maintain the pace followed by developed nations in Europe either because the country was not able to, did not know how to, or did not want to (frequently all three). This had not occurred before (it is enough to remember the important ecclesiastical developments and the influential pedagogical movements already rising in Spain in the Middle Ages and at the beginning of the Modern Age). From the Enlightenment onwards, things changed. From the moment the authorities in the majority of European countries decided to steer a course in the then rising education systems, Spain started to react with apathy, lack of interest and even, sometimes, with the firm objective of not embarking on a course which stirred open suspicions. The Spanish intellectuals warned of this, but they were not paid due attention. Manuel de Puelles describes in his last book the system outlined in the first decades of the eighteenth century as a ‘frustrated national system’.² It is true that there were reactions, but untimely, late and almost always timid. The Quintana Report in 1813 was one such and, in the middle of the nineteenth century, the Moyano Act another that lasted a hundred years before a complete new legislation replaced it (the laws that came to light in that period were of more or less importance but always partial and referring to a certain level or particular aspect). There were always, in different periods, considerable efforts and ambitious plans. But either they did not reach a satisfactory conclusion or, in some cases, they had to be withdrawn being considered too daring by quite a number of Spanish people.

The reasoning that Spain should reach the same level as the most advanced countries was common but on many occasions was counteracted by the isolationist mentality prevalent for a long time in the country. As Menéndez Pidal emphasised, the resistance of many Spaniards to listen to those from abroad, or to try to relate to them, goes back a long time. After the evidence that the Venetian Tiepolo had already given in the sixteenth century, Menéndez Pidal acknowledges in this resistance as a kind of historical constant, enduring forever, and he concludes

[I]solationism prevails in Spain ... considers that the Spanish have little to learn from other peoples and that it is essential to preserve intact all traditional forms of life and thought free from any foreign influence which only serves to weaken and endanger them. Feijoo’s many arguments against these two prejudices are just as important today as they were then.³

That ‘today’ referred to by Menéndez Pidal was Spain in the middle of the twentieth century. Things have certainly changed a lot since then. Not long afterwards, Spain set out on a decidedly European journey. The General Act of Education of 1970, promulgated in the latter stages of Franco’s time, without doubt opened the boundaries of the education system to outside currents and it was, for this reason, severely judged by many political and social authorities of the time, including many intellectuals.

However, and in spite of all its qualities, this law was not able to make up for lost time. It had to conform with eight years of compulsory schooling, as it had been before, due to the high number of young people absent from the secondary classrooms from the age of 14. By this time, many European countries had already increased the number to nine or ten years. This law, however, dared to apply the ‘principle of comprehensive education’ or integration of primary and early secondary levels even before other countries such as France, Italy or, indeed, some northern countries. But what constituted an irrefutable advance in 1970 was, 20 years later, reiterated, at an inopportune moment, and exaggerated by the new Act (known in Spain by the LOGSE) which raised to ten years both compulsory education (which was a good decision) and comprehensive education. By then, the majority of our neighbouring countries were already revising the application of this last principle (comprehensive education). I will return to this point. What interests me at the moment is to highlight this tendency to delay which Spanish people cannot overcome in educational matters. Delay as much as the time of carrying out measures as in revising their effects, is not always positive.

Despite the isolationist temptations and the huge lack of attention given to the experiences of others, there have always been people convinced of the need to go abroad, particularly to Europe to look for those things worthy of admiration and, if possible, incorporate them into their own educational habits. It is not possible for me to cite here the many quotations which confirm this tendency. It is enough to acknowledge the statement that, even at the start of the twentieth century, the minister Romanones included in his preface to the important education Decree of 1901:

Nobody can deny that all essential reforms implemented in our national education come from people who have lived in communication with scientific European thought, who have travelled abroad to later sow within their own homeland, a land as fertile in its talent as it is abandoned in its growth. This is demonstrated, in the history of Spanish education, by the pedagogical current which flows from the humanism of Luis Vives to the nursery schools of Montesinos.⁴

In the first decades of the twentieth century, references to abroad had become proverbial in Spanish political circles. The Board of Widening Studies (‘Junta para la Ampliación de Estudios’) was decisive in this respect, an institution itself motivated by European ideals (especially German) which for the most part involved sending Spanish scholars to European centres in order to collect educational experience. The Second Republic marked another key moment in this internationalist thirst, looking outside – from western countries to the Soviet Union – for legislative realities and experiences relevant to the country. During the first times of Franco’s rule, a period of distrust was experienced which inclined to blame the evils on foreign influences. But even in Franco’s dictatorship a substantial change took place in this regard. As mentioned above, one of the arguments which certain sectors brandished against the General Act of Education of 1970 was that of succumbing to the splendour of the foreign and bowing down to the international criteria of UNESCO. Since then, the references to Europe and the developed world in general have been constant in all

the education laws, including the four laws implemented during the socialist period, 1982–1995, the two elaborated by the conservative government between 1996 and 2004 and, finally, that implemented at the end of 2005 by the socialist government elected a year before.

But precaution in the face of the foreign has never totally disappeared. The accusations of ‘foreignism’ abounded throughout the nineteenth and twentieth centuries and still abound today. Certain travellers from other times, when presenting their reports, seemed to beg pardon.⁵ Some of them, as with the following, expressed their opinions particularly sensitively and prudently:

All imitation of the foreign, be it German, French or English is inappropriate in Spain where we are not French, English or German: on the contrary, it is best to understand and study what is next to us, to study what is ours and compare it to what is beside us and notice those things that the differences make us see and all that resemblance or equality can be of use to us.⁶

This leads us to another interesting aspect: the Spanish propensity to look for confirmation abroad of their own theories. The ‘partisan’ vision of foreign experiences is something which has been denounced for a long time. History continues, in this case as in all cases. The fundamental novelties of our time are the erratic comparisons between Spain and abroad made by the mass media, especially the newspapers. The majority of Spanish newspapers from time to time dedicate their pages to writing about reforms, innovations or simply ‘events’ related to education in other countries, particularly European. In general, those who write these articles or commentaries are journalists residing for a short time in these countries who intend to give general information and who treat education as lightly as they treat political elections, health problems, etc. Characteristic of these articles is their decontextualisation and oversimplification. But because they are considered useful to the reader, the newspapers call on them.

I will also refer to another trait which I consider important when contextualising ideas existing in Spain about its own education system. This old trait, still present, is based on what many Spanish people have defined as the ‘age-old backwardness’ of Spanish education as regards the European setting and, more in general, the developed world. The principle thesis is to explain this backwardness as a result of the political difficulties of the country (past and present). To put it another way: in Spain, the underdeveloped education was and is the result of an underdeveloped politics.

This affirmation is latent in many of the criticisms made of the education system, as much in academic and political circles as in trade unions and guilds, etc. On the one hand, these critics consider in detail everything related to the economy and investments in education (the lack of adequate funding being constant every time an education law is planned or developed). However, on the other hand, the legislation itself insists that Spain be on the same educational level as the nations around it. The vast majority of laws implemented or bills passed dedicate at least a number of paragraphs to declaring the need for Spain to ‘homologise’ with the rest of the European countries or the developed world. It is a pious way of admitting that Spain is beneath these countries in legal norms or in implementation, efficiency or human resources or materials. In Spain educational comparisons are of a highly plaintive nature.

Does the same apply to other countries? I sincerely think not. If we examine, for example, the main laws and legislative measures of other countries of a similar or superior development, we do not find in them the lamentable comparisons to which I refer. On the contrary, the necessity for legislative change is seen in virtue of the countries' evolution or indeed in virtue of the deficiencies observed in the former legislation, but not in virtue of feeling 'inferior' to the others. It seems to me we are faced with something particularly Spanish also shared by some other peoples (perhaps in some Latin American countries).

I would like to refer to another characteristic of recent Spanish education history: the continual making and remaking of material in education policy. Since the restoration of democracy in 1978, every time the governments change in Spain, Spanish people witness the same repetitive, tiresome scenario. The government which comes into power insists that the former government has made a mess of educational matters, and that it is the former heads' of state and their laws' fault that the children's education is in a pitiful state. They try to show this in different ways (to prove it is more difficult ...) and all in a hurry so that they would not be reproached for what others have done. Furthermore, they act with the infantile belief that their government will benefit these educational matters immensely. If they can, they change the former government's laws, intrinsically bad, purely because they have been promulgated by the others. Embittered criticisms pour down on the former teams. Year after year, it is the same without realising that it is those who are in government for one, two, three or more years who are the ones criticising and that things, rather than getting better, are getting worse. And this incites the following government, whatever its colour, to do the same. I think this discontinuity in the Spanish education policy, apart from being profoundly damaging, strongly contrasts with the conduct of other countries of the European Union. Although their policies may undergo certain touching up, never are they subject to the making and unmaking which characterises Spanish contemporary education.

The Politico-Administrative Macropblem

Without doubt the most outstanding event in recent Spanish education history is that of having converted the education administration from strongly centralised to furiously decentralised. Furthermore, this has happened in a very short space of time. In a very few years, one of the firmest and longest-lasting characteristics of Spanish education has been dismantled. And, as to be expected, with doubtful results. These days, to wonder at the existence, already present or about to be applied, of 17 different education systems in Spain (one for each Autonomous Community) is not simply work of the imagination.

Does the process followed by Spain correspond to that of other countries, above all, to those nearest the Spanish cultural and economic environment? Seeing that, today, it is these countries which have the most influence educationally in the international arena, and it is important to briefly consider them.

The first thing to remember, in this respect, is that, in the terrain of educational policy, as in others, to decentralise has already been fashionable for decades encouraged, above all, by the Anglo-Saxon tradition. This decentralisation carries the

implicit idea that it facilitates the efficiency of political action, especially by bringing the administration closer to the citizens and by assuring their participation in the management of public interests. One way or another, the impression is given that decentralisation is something naturally required by democracy and that ‘centralist’ actions involve a certain idea of inappropriate control. The practice of so-called democratic centralism on the part of communist regimes which appeared after the Second World War confirms this theory. Few were the previous communist countries which, in the second half of the twentieth century, did not embark on processes more or less inclining to decentralisation. Centralism defined as ‘right wing’ (from those brought about by Nazism or fascism to those started more recently in other countries) were especially criticised. Francoism was, in this sense, the object of strong criticism from both outside and, especially, from within Spain. The surmounting of Francoism meant essentially, for most of the political powers and the Spanish intellectuals, a surmounting of centralism and the adoption of decentralist criteria. The ‘homologation’ of Spain – educationally and otherwise – with countries in our cultural context seemed to require, for a start, decentralisation.

As mentioned, the models particularly relevant have been those of the Anglo-Saxon tradition and, in particular, those of the United Kingdom and the United States of America. In both territories, the standard adopted, in cultural matters, is complete regionalisation (we cannot talk of ‘decentralisation’, in my opinion, given that it was not started from a centralist regime). With regard to the United Kingdom, regionalisation has been dominated, since the nineteenth century (with strong roots in its past, without doubt) by the idea of ‘local administration’ of the system, controlled by the Local Education Authorities (LEAs). In the case of the United States, regionalisation is controlled through the state administration in that (since the American Constitution) the educational responsibility corresponds to the States. However, if we are to take note of the predominant tendencies in both countries since the middle of the twentieth century to our own time, we would have to define them as ‘centralising’ tendencies without distortion of the former regionalising core. There appeared in both countries, in this period, national Ministers or Departments of Education which did not exist before, in the United Kingdom in 1944 and in the United States in 1979. From those moments on, these Departments have taken more and more control of specific tasks despite the more or less declared resistance of the LEAs in one case and the federal States in the other. That tendency has not slowed down in either case up to the present and it may be said that, in fact, it is shared by all the political forces in both countries. In other words, these countries’ conduct in the last few decades seems to indicate certain caution in the problems caused by excessive regionalisation or decentralisation in the matters that concern us here.

In continental Europe, something similar may be affirmed with respect to the country which is most based on a federal administration – Germany. Despite the fact that it is the *Länder* and their respective Ministers of Education which hold maximum responsibility in educational issues, the Federal Ministry of Education has been increasing in importance since its creation in 1969. Most importantly, while a large sector of the population and political life attribute the deficiencies of the education system to educational regionalisation, the calls for a greater federal intervention are frequently repeated. It is foreseeable that this intervention will come about in the following years (in fact it is already happening, particularly in third-level education).

It is true that decentralising tendencies have made a way forward in certain European countries. This has been the case, for example, with the Scandinavians who, because of the size of their population, work, logically, upon a predominantly centralising base. However, this has been, nearly always, decentralisation of a local nature, rather than regional. This is to say that in education policy matters, decision-taking by the town councils and other local authorities has gained ground. This, without recurring to territorial distribution of decision-taking on the part of provinces or regions.

With reference to the political habits of strongly centralised countries, such as France or Italy, the process has tended to fortify their own territorial demarcations with more responsibility to, in the case of France, *les Académies* and in the case of Italy, *le regioni*. But in both cases, the relevant administrations have always been peripheral administrators, always under the aegis of Paris or Rome. Basically, this means a decision-taking reduced to only certain matters of enforcement and rarely in matters of greater magnitude. Far from what is happening in Spain, Italy is today a basically centralised country in educational matters. Similarly France; as before, its *décentralization* has consisted, as they themselves admit, more in *déconcentration*. We can say the same referring to countries of southern Europe, such as Greece or Portugal, without ignoring their decentralising efforts.

These efforts have also been carried out in countries in Eastern Europe, heirs to 'democratic centralism' which was imposed by communism and which they abominate but from which they have been unable to escape until now. In sum, there is only one country in Europe which, even before Spain, has carried out such a marked division of functions in its territories: Belgium. The motives of this small country have been of a cultural and linguistic nature, for a long time based on living traditions, thus understandable to a certain degree; but the educational situation there leaves much to be desired, politically and qualitatively speaking.

The conclusion reached, then, after this journey through the education policy of Europe would be, without doubt, to confirm the prevalence and probable continuity of conciliatory and moderate positions in this subject, positions that seem to flee from excesses and rather correct from excessive centralisation or decentralisation. At the same time, it is obvious that globalising movements bring countries everyday closer to one another, closer also in the similar educational matters adopted in each country. Certainly, movements of resistance which insist on the richness of indigenous cultural values are more and more energetically against that globalisation which endangers rich cultural resources by an impoverishing uniformity.

However, usually, these movements stem rather from *local* geographical units than from *nationalist* desires, now outdated.⁷ 'Globalization' incites what has been called 'glocalization' but not 'glonationalization'. We will surely end up recovering the original concept of *natio* as place of birth (the small space in which each of us was born). Almost everywhere, one has the impression that the experience of nationalisms, in political terms, has not been very positive lately, although it may have been in other moments of history.

Returning to the case of Spain, the future being forged very little resembles these world tendencies. Due to the pressure of certain group interests, of political classes and of a part of public opinion, the Spanish *nation* appearing at the end of the fifteenth century and strengthened throughout five centuries seems to be today separating into

other *national units*, of a still uncertain number. Some politicians have openly referred to this phenomenon as a process of ‘disjoining’. On the other hand, the road to follow is not clear. Already present in the spirit of some political parties, specifically the Spanish Socialist Workers Party (PSOE), at the start of the transition from Franco’s time to democracy, was the idea of a federal Spain. This contemplated, however, the permanence of the Spanish nation and the admission, perhaps, within that, of various federal States. But this discourse, which has remained detached from the historical evolution of Spain, has today been proven wrong. Those who today claim a new political structure do not seem to be satisfied by converting their territories into States, but into States and Nations at the same time. This means, without doubt, the assumption of a total national sovereignty and a total state administration only tempered by the desire to remain in the European Union. This is the aim of the nationalist discourse, although it recognises a time of gradual approach in which the possession of their own education systems (national systems in its oldest meaning) is decisive. To make way for these (their own) education systems is not something that can be left for tomorrow or the day after. This is something which must be started immediately. This explains the pressures to obtain the text which has finally prevailed in the recent ‘Ley Orgánica de Educación’ (Education Act) in 2006. For different reasons, the majority of the political powers have associated themselves to this ‘disjoining’ project of the Spanish education system although it is not known how widely it will extend or even what results will be obtained. Only one political party has opposed this, the Popular Party which, however, represents the views not only of numerous voters, but of many of the Spanish people.

What will the immediate future bring? Will the existence (perhaps not yet legalised) of various *national* education systems within an already theoretical Spanish education system be accepted? If so, it seems improbable that these systems will be only a few in number and, more concretely, they will be systems that claim as motive their condition as ‘historic’ territories. However, in the normal evolution of events, it may be that, in the beginning, those who decide to follow this model will be these ‘historical’ territories and that the others will limit themselves, as time goes by, to later reclaiming the same prerogatives. It is also possible that these latter, tired of so much struggling, later decide to reconstitute a limited Spanish education system, reduced to the Spanish-speaking territories. This is surely the most desired for solution by the self-denominated ‘historical nationalisms’ who trust in the power of that line from the pen of the great poet, Antonio Machado: ‘the walk is made by walking’.

What will be the future? Four or six education systems having recourse to their own languages? Seventeen education systems each having recourse to the same measure autonomy, the highest measure? One Spanish education system with certain regional modifications? It is difficult to predict the final result. At an international level, the prevalent powers support internationalising movements, the approximation of the distinct national systems, and the elimination of educational frontiers. At a Spanish level, the prevalent powers support, as we have seen, nationalising movements, the distancing between systems, the construction of new linguistic, microcultural and perhaps, socio-economic and even (supposedly) ethnic frontiers. It is not clear if this dialectical conflict will lead to some surviving synthesis. At the moment, the only certain thing

is an inconclusive period of uneasiness and doubt which will slow down, in many aspects, the international competitiveness of Spanish education.

More obviously, the 'disjoining' tendency to which I have referred has had a clear repercussion in education administration. Bureaucratic proliferation is an evil which the administrations of all countries suffer in one form or another. Nor is this something of an exclusive trait of the democratic world (remember what happened in communist countries) but neither has the evolution of democratic societies succeeded in putting the problem on track again. It is enough to take a look at the respective web pages of the Ministries of Education of European countries to understand that, in nearly every case, they are composed of huge structures, with numerous civil servants. And it is the same when, in regionalising or decentralising countries, one tries to penetrate the structures of the decentralised units. However, I think that Spain has surpassed itself in this tendency and finds itself today among the countries which support the most obese education administrations.

What seems true is that in nearly all developed countries there is a concern to lighten the structure, to 'recover one's figure' which, on the contrary, does not seem to be the case with Spain, at least at the moment. The Spanish politicians are far from taking seriously a similar campaign to that which, a few years ago, the French socialist minister Claude Allègre started with the slogan *il faut dégraisser le mammoth* ('the mammoth must lose weight'), without doubt, referring to the massive French Ministry of Education. The irresponsible proportions of the 'Welfare State' still do not worry the Spanish. In Spain and in its 17 Autonomous Communities the tendency is to go on putting on weight administratively speaking without asking if the bureaucratic size of the prolific administrative personnel is really justified with regard to the tasks assigned and above all, if there is an acceptable relation between benefits and losses. Trade Unions, associations and groups which never stop demanding resources for education rarely wonder if the expansion of these is not excessive or even counterproductive. The thirst to create new dependencies seems to know no limits, despite knowing that these new dependencies produce more complications and curvatures in management and the consequent need for more human resources.

Further, in the case of Spain, a discoordination between central and regional structures (and among the regional structures themselves) can be clearly observed, a discoordination not common in other countries. Indeed, the correct homologation of respective functions in non-central administrations is never easy. A few years ago, the German chancellor, Schroeder, gave a good example of this when he blamed the poor results of the German education system in the PISA on the attitude of many regional authorities (the Ministers of the *Länder*). But on this point Spain has reached insuperable levels compared to other countries. To know how to deal with the central Ministry of Education in some autonomies is going to be very difficult, unless it is prepared to commit *harakiri*.

No one can doubt that the quality of education in every country depends on, as a fundamental component, the better or worse operative capacity that its administration possesses. An efficient administration is indispensable for the achievement of its educational objectives even when it is known that that administration does not correspond anymore to the reality of the times. Many have criticised, for example, the fundamentally centralist and bureaucratic scheme of the French administration but few doubt that it is an administration which, in general, works

well. Something similar could be said about some non-European countries like Japan, despite its verticalism and its frequent inflexibility, or the United States, despite the prolific variety of its management behaviour. These and the education systems of other countries can and do have considerable defects, but they are well-articulated, well-led systems which work, which aim at clear and precise objectives, putting the adequate mechanisms to work in order to attain them. They are systems whose legislators make laws according to their understanding of the country's necessities, the leaders make decisions according to the legislation, the consultant organisms really consult, the inspectors supervise and control, and the teaching and administrative workers do the work to which they have been assigned. People do not agree there that, simply because they live in a democracy, such duties should be in some way shared or discussed among everyone, disseminated, altered by momentary circumstances or different pressures. If, occasionally, the opposite occurs, the mechanisms in society immediately denounce and correct the faults. Without unnecessary alarm, I don't think the same can be said about the Spanish education system.

A few words more, finally, about the perennial contentiousness existing between the public and the private sectors. Also it is time that Spain, in this aspect, brings itself up to date and reaches stable solutions of compromise. Even in Italy, where the private sector has always been quite reduced, left-wing men have defended (Minister Berlinguer did so a few years ago) the complete *parità* between both sectors. Countries traditionally structured on a strong public sector are today making insistent calls for the collaboration of the social initiative. Spain, on the contrary, has a very old tradition of non-state schooling, without whose collaboration the system would be a disaster (more than 30% of Spanish students attend non-state centres). We cannot go on listening to chants from the end of the nineteenth century or beginnings of the twentieth century that tirelessly repeat themselves in favour of a 'single, public and lay' schooling and against financial state aid for the centres of social initiative. In Spain, both sectors need one another if an education administration abreast of the times is to be attained.

Some Problems of Homologation and Quality

As I stated at the start, this last section of the chapter will be dedicated to describe as clearly as possible some of the peculiarities of the Spanish education system in contrast to the general situation in countries of the European Union. Far from being an exhaustive enumeration, I have chosen what I consider to be the five most relevant problems.

A Deficient Conception of Compulsory Secondary School

The General Act of Education of 1970 had applied, already as I have said, the 'comprehensive principle' between the ages of 6 and 14, to the Spanish education system. During this period, students from all centres, public and private, were obliged to follow the one curriculum, common to all and uniform in every detail. The 1990 Law, while amplifying obligatory education to 16 years of age also applied to all students up to this age an identical curriculum. And this in spite of the fact that the majority of the

European countries had already corrected the criterion, looking for formulas of a certain diversification which would serve the real interests and capacities of the students, especially between the ages of 14 and 16. With a few changes of little importance, the Law of 2006 has persisted in this line with the result that a high percentage of students have become completely uninterested in their studies (those colloquially called 'student objectors'). In this important educational period (between the ages of 12 and 16), the Spanish education system gives an image which lacks realism, an image of camouflaged inequality, of inefficiency and of a capacity for conflict which strongly contrasts with the education policies implemented in these years in nearly all the countries of the European Union.

Clearly Limited Duration of Advanced Secondary School

Having finished compulsory secondary education, students can choose between vocational education or what is called 'bachillerato' which leads to advanced studies lasting two years (between the ages of 16 and 18). The majority of students choose this secondary education, divided into a few branches (fine arts, science and technology, humanities and social sciences) but still with a strong common trunk. It is nearly unanimously agreed that, in this short time, taking into account the above-mentioned deficiencies of advanced secondary education, it is nearly impossible to provide the students with the necessary abilities to attend, with sufficient guarantees, university studies. Furthermore, not one single country in the European Union has such a short period of advanced secondary education. Some Spanish politicians have defended themselves saying that the British *sixth form* is of a similar formula but they are obviously mistaken: while the *sixth form* is a time of intensive dedication to a few specialised subjects, the Spanish 'bachillerato' contains a curriculum of 10 or 12 subjects. As a result, it is usual that Spanish students, starting university, have a training which is qualitatively lower than their European counterparts.

High Rate of School Failure and Mediocre Results

In Spain, one in every four 14-year-old students is in a situation of obvious or hidden failure, a proportion which increases at 16 years of age, to one in every three. These data are being insistently repeated in numerous national and international evaluations. Besides being very worrying facts, they are not so worrying, in my opinion, as the following evidence: the number of Spanish students who reach high grades ('excellent') are barely 4% at the end of compulsory education.⁸ This means, quite plainly, that the *mediocrity* of the results is, perhaps, the most illustrative fact of the Spanish education system.

Although these results may be due largely to the deficiencies I have demonstrated, it is the almost unanimous conviction of the specialists, the teachers and Spanish society that the roots of this problem are much deeper. In either case, both facts considered together (high failure rate in school and general mediocrity), it seems clear that Spain is one of the lowest ranking among the countries of the European Union, in the company of, perhaps, only a few others. Spain cannot easily contribute to improving the general situation of education in Europe if it persists in its present plans.

High Level of Teacher Demotivation and Deprofessionalism in School Direction

The first problem I mention here is not something that affects exclusively or more seriously the Spanish education system than other European countries. However, it constitutes a deficiency which may put at risk the collaboration of the Spanish teaching profession with that of other countries when the time comes to build, from the school, a climate of European citizenship and indeed, that improvement in quality in which the directors of the European Union insist.

The demotivation to which I refer in Spain has fundamentally social and political roots and not, as occurs in other countries, economic and labour roots. The economic treatment of the Spanish teaching profession, without being to my mind the most desirable, is however, above the European average. They are also above the average regarding other aspects of teaching life: working hours, teaching hours, student-teacher ratio, number of students per classroom, etc. (it is true that in these aspects there is quite a lack of proportion between the public and the private sectors, in favour of the former). However, the proportions of sick leave, requests for early retirement, situations of stress and above all, despondency have done nothing but increase in the past years (and precisely more in the public sector than in the private). The fault seems to lie in the lack of social esteem in which teachers are held (beyond merely rhetorical appraisal). A climate of growing uninterest towards learning on behalf of the students and indeed many families and also a clear increase in indiscipline and indeed violence (above all, verbal) contribute to making their work in school, at best, disagreeable.

Added to this is the continual disintegration of the directive team in the last 20 years which is in Spain, contrary to nearly all the European Union, completely deprofessionalised. The insistence in the necessity (which I don't doubt) of the participation of everyone (students, parents, personnel) in the life of the centre has led to the confusion of participation with leadership, that is to say, the one instead of the other.

The problem affects principally public centres where it is not uncommon that not one of the teachers applies to cover the directive posts. Although there are, without doubt, praiseworthy exceptions, many Spanish schools suffer a climate of mismanagement. It is obvious that the main responsibility of these things lies with the inadequate policy of human resources in education and, in particular, a repeatedly mistaken legislation in such important matters.

Homologation Deficiencies in the University Sphere

The two traditional tendencies which I mentioned at the beginning of this chapter –isolationism and Europeanism – are particularly present in what is referred to as 'educación superior' (tertiary education), a term which in Spain means university education (in fact, there is no form of tertiary education since the reform of 1970 apart from university). If, on the one hand, we can see abundant 'Europeanist' rhetoric flourishing in all universities, on the other, isolationism is continually present, even favoured by a legislation itself caught up in the dynamics. I write these lines when a new law is just appeared which, in spite of its initial pretensions of Europeanism and substantial change, is no more than a superficial retouching of the anterior law of 2002 which was itself no

more than another touching up of the 1983 law, a law not so ambitious itself regarding the drawing-near of the Spanish universities to the European ones. Under the pretext of giving higher levels of autonomy, what is really being done is, on the one hand, subjecting the universities to a higher dependence on their respective Autonomous Communities and, on the other, confirming habits of university management and study plans that, instead of helping, practically hinder that which is known as the 'Bolonia process'.

There is a serious risk that the situation of isolationism may affect, in Spain, not only the 'common European space of higher education' but the universities themselves. The inbreeding of the university teaching profession is, in Spain, an old deficiency, recognised and criticised by all, but what the legislation seems to bring is rather than procedures to fight this, new means to foster it. It will be difficult soon to find professors in the Catalan universities who are not Catalan or in the Andalusian universities, professors who are not Andalusians. These are merely examples, applicable to the other Autonomous Communities. It is even probable that it will be easier to find in them an English or German professor rather than a professor from elsewhere in Spain. In all, the risks of isolationism do not derive only from an inadequate policy of selection of the teaching staff but from other crucial aspects such as study plans and qualifications which, instead of converging, can even have a separating effect.

At the moment, despite the manifestation of Europeanism of many politicians and university authorities, the unanimous conviction exists that Spain will not be fit to adequately compete in 2010 within the so-called European space of higher education. Too much time is being lost. If we look at the international evaluations, the image of the Spanish university from without is quite poor; although one can criticise them, evaluations such as that of Shanghai, *The Times*, etc., place Spanish universities in positions far from the top, and, without doubt, this creates an unfavourable state of opinion. However, in contrast, Spain is now the country which attracts most students in the Erasmus programme. It seems clear that the factors which determine this attraction are not so much to do with the prestige of the Spanish universities but rather other factors: language, climate, tourist attractions, cost of living, etc. Even so, the facts are very positive because, above all, they can be used by the Spanish universities as an element of international diffusion; if what initially attracted certain students was not the classrooms, the professors or the quality of studies, these could still end up being so. The Spanish academic authorities should use this good news not as a tranquillising element but rather as a challenge to really improve its institutions.

Notes

1. A more balanced critical outlook is given in my latest book: *La máquina de la educación. Preguntas y respuestas sobre el sistema educativo*. Barcelona, Ariel, 2006. In fact, most of the ideas developed in this article have been taken from that book, there contrasted with more openly positive aspects of the system.

His arguments have been energetically reproduced in present-day works such as Gred Garrad: *Ecocriticism*. London, Routledge, 2004, pp. 118–119.
8. In order not to abuse of references in relation to evaluations, I refer the reader to the last two PISA surveys, of 2000 and 2003. Consulting the web page of the Evaluation Institute, an organisation belonging to the Spanish Ministry of Education, ample references and concrete figures may be obtained.

EDITORIAL INTRODUCTION: THE NATIONAL, THE INTERNATIONAL, AND THE GLOBAL

Robert Cowen

Once upon a time, I suggested that comparative educationists ‘read the global’. I distinguished this permanent task from its contemporary universalising answer (‘globalisation’). ‘Reading the global’ in comparative education is the selection of an agenda of academic attention, the naming of anxieties and puzzles embedded in an interpretation of those foreign parts of the world which are ‘seen’; in the sense that those places are deliberately raised to visibility.

Thus each generation sees different things when it thinks comparatively about education; at the end of the nineteenth century, the Chinese were very alert to Japanese progress – in the middle of the twentieth the Chinese saw the USSR; Tolstoy worried about Western influence on the Slavs – Russians in the future were to worry about the strength of their influence on the Baltic states; Max Weber as part of his thinking about industrialisation and rationalisation analysed the rise of ‘the expert’ – now our experts ‘develop’ economies and ‘experts’ elsewhere.

Professionally, the ‘reading of the global’ keeps changing: it is the set of first-assumptions, by a new generation of comparative educationists, about what is significant in the social world upon which they are trying to act (Horace Mann or Torrey Harris) or, with the academic comparative educationists, to think about. A later generation of academic comparative educationists would read their ‘global’ differently: perhaps stressing that States are either totalitarian or democratic; that national character is important; that progress is linear and likely; and that Empires are benign. When there is a major disturbance in any one or two of such assumptions, the agenda of attention changes, rapidly, again. New assumptions and new agendas of attention redefine the field of study: States are either communist or democratic; identities are not secure – we live in a ‘post-modern’ world; Empires are bad and they mutate into neocolonialism; anyway progress is not linear. With the shift in agendas of attention and anxiety, academic departments rise and fall in reputation, comparative education becomes more (or less) sociological, less (or more) policy-oriented, more or less tightly linked to official agendas of action.

With the shift in agendas of attention and anxiety, there is also a shift in *episteme* – the academic perspectives utilised in analyses or in descriptions alter (Cowen, 2003). Thus a concern with ‘forces and factors’ – useful in understanding the educational patterns of late nineteenth and mid twentieth century Europe via struggles over language and religion and political programmes such as ‘communism’ or fascism and ‘democracy’ – is replaced by

an effort to offer precision in policy advice. The world is seen as sufficiently stable to be able to concentrate on gradualist reform and fine-tuning of educational systems.

Of course the world ('the global') was not like that at all. It was violent, revolutionary and dangerous. In this time period, major events included the Hungarian Revolution and the invasion of Suez and the beginnings of the Cuban Revolution. But the bit of the global which the comparative educationists of that generation were choosing to see was open to improvements through the application of social science in (urban reconstruction, health care, social policy as well as) education in one or more worlds; and that included the homogenised category, the 'Third World'.

It is not merely what the global actually is; it is how the global is read which also defines the agenda of attention in comparative education.

As a consequence, the 'voices' of comparative education do not begin to sing from, as they say, the same hymn sheet. The debates are not cumulative. The old voices are silenced; become *passé* – they are reading the 'wrong world'. New agendas of attention and anxiety displace the normal puzzles (about equality of access to education, changes in curriculum, the improvement of teacher education and so on) popular in the period of conviction about the power of 'scientific method'. New guilt about neo-imperialism draws into comparative education radical and critical theorising from Chile or the Mahgreb or from Brazil. The political world itself is reread: China becomes as important as the USSR while India continues to remain almost invisible. The people who populate the stage of comparative education are newly noticed: the Scots; females; the Third Age; 'invisible' minorities such as the Koreans in Japan are made visible. *Epistemes* change: anthropology will be helpful; a 'linguistic turn' occurs; 'thick descriptions' of a variety of kinds will contextualise meanings comparatively.

Currently, it could be argued that we have gone through such a shift in 'reading the global'.

The end of the nation state was discussed – and with it, on a slightly nervous note, it was announced that therefore comparative education was finished: a variation on the motif of 'the end of history' – and so the study of history ends. The alleged end of comparative education occurs with the alleged end of the nation state. That is a shocking thought; but of course it is also a quirky thought based on an odd reading of both the global and of comparative education itself.

It is only partly true that comparative educationists studied the nation state. Most of them chose a personal unit of analysis to pursue their own agenda. They studied correlations; problems and problem-solving; civilisations; and cultural envelopes. Few scholars, Mallinson (1966) is one, explicitly pinned their work simply to the national (in Mallinson's case, via the concept of 'national character'). Most of the other comparative educationists of that generation used the nation state as the source of their illustrative narratives while they worked out their own core intellectual or theoretical problematic; such as making comparative education more useful at critical moments of decision. Of course they knew much about particular nations; but there was always a *tertium comparationis*.

In addition, as that generation of comparative educationist set about their work what they discussed analytically was the transfer of educational ideas, principles, policies,

institutions and institutional practices. However, they justified themselves through selections from Sadler's writing and thus a great deal of work was indeed done on one aspect of the transfer problem: the theme of the social contextualisation of educational systems – how they are embedded in their societies.

This problem can be called the *osmotic problem*: the relations between what is outside of the educational system and what is inside. How does that relationship work and what will you call it – hence the trajectory of work in which Hans struggles with his 'factors' as an interpretative tool; and King writes (rather unhelpfully perhaps) of 'total contextual dynamics'; and Holmes (rather clumsily perhaps) writes about his three 'circles' – norms, institutions and environment. Thus the classic triad at the heart of the problem of thinking about comparative education becomes unbalanced.

The classic problem of comparative education is made up of three moments (i) '*transfer*'; (ii) *translation*: the double-osmotic problem of the social embeddedness of educational ideas, principles, policies and practices in one place and their insertion into another social location. Later, there is (iii) the *transformation* of the educational phenomenon as it 'grows' socially, osmotically, in its new place.

If the work of comparative educationists is construed in this way then there is a continuous problematique which comparative education addresses – although the continuity is hidden as scholars concentrate their efforts for some years on one aspect of the triad rather than another; and perhaps lose sight of all three as a set, as a triad, of relations.

Thus – it is being suggested – there is, at least, one deep continuity in what comparative educationists have been struggling with. They have been studying, with some oscillations in agendas of attention and in epistemic approach, what Roberto Albarea (2006) includes in the concept 'The Betweenness'. Aspects of that 'betweenness' are being well explored currently under the label of 'globalisation'.

This is the current effort to redefine the interpretative concepts used to address new international power relations and the structuring of the world system. For each generation of academic work, these concerns include – at various levels of sophistication and theoretical alertness – the social spaces and space-time relations through which ideas and practices flow, internationally and transnationally. What fills the spaces? What shapes them? What flows? How does whatever has 'flowed' change its social shape as it is domesticated?

Sometimes 'transfer' is at the centre of the work of particular scholars for some time, but it is the triad of transfer, and translation and transformation which stabilises comparative education, not merely an exploration of one form of transfer, or one way to study it. Jullien posed only one small part of this problem for a modern (and a modernist) comparative education and he posed it in a relatively trivial way by emphasising (in contemporary jargon) robust data and evidence-based practice. No wonder it has been difficult to recover from that simplistic position. Academic comparative educationists have been struggling to configure the academic problem, to extract and stabilise the themes of the triad, ever since.

Perhaps, now, we are getting there. The chapters in this section are all very much centred on these problems: the relations between the national, the international and

the global; The Between and shape shifting. Almost all chapters redefine the social space – and time – of The Between; almost all chapters show inter-national and transnational mobilities and their new patterns and agents. All chapters address in different ways the issue of ‘flows’. All chapters raise explicitly or implicitly the question of ‘translation’. The range of questions and the answers outlined in this section are extremely interesting.

WHO IS STROLLING THROUGH THE GLOBAL GARDEN? INTERNATIONAL AGENCIES AND EDUCATIONAL TRANSFER

Jason Beech

In 1900 Sadler warned against the transfer of educational policies or practices from one context to another by noting that ‘We cannot wander at pleasure among the educational systems of the world, like a child strolling through a garden and pick a off a flower from one bush and some leaves from another, and then expect that if we stick what we have gathered into the soil at home, we shall have a living plant’ (Sadler, 1979: 49).

At those times, the ‘children strolling through gardens’ were mostly men (sic) who were appointed by their governments to develop their own systems of education. These travellers and reformers believed that by studying other educational systems, such as Prussia and France (two of the most popular gardens of the nineteenth century) they could avoid some of the ‘mistakes’ made by other countries in their linear progress towards an ideal educational system, and, of course, they could find some aspects of these systems that could be adopted at home.

Even though Sadler’s lecture has been given much attention, and the above is probably one of the most quoted sentences in the literature (in the English language) on comparative education, his advice was not always followed. Educational transfer has been the *raison d’être* of what has been called ‘applied comparative education’ (Cowen, 2006). Since the times of Jullien, Victor Cousin, Horace Mann, Tolstoy and Sarmiento, practitioners of comparative education have given policy-oriented advice about which educational ideas, practices or institutions overseas could be transferred as the solution to pressing internal problems.

So, for example, when the Japanese were faced with the ‘Black Ship’, which revealed their technological underdevelopment, they saw education as one of the ‘secret keys’ of the power of the West (Passin, 1965). If Japan wanted to compete with the West it had to borrow Western education. European educators were hired to run institutions in Japan, and Japanese leaders and intellectuals were sent to Europe and North America to observe educational practices (Tanaka, 2005). The administrative model was taken from France. Co-educational common schools as the basic unit of the school system, normal schools and vocational (particularly agricultural) education were transferred from the USA (Passin, 1965); and German Universities were taken as a model for creating the Imperial University (Tanaka, 2005).

Similarly, in the late 1950s, when the USSR launched the first artificial satellite, after the failure of two US attempts, there was a great shock in the USA. The Sputnik

crisis was conceptualised as an educational failure. American schools were criticised for their repressive nature and mindlessness (Ravitch, 1983). One solution was ‘found’ in the English infant schools. Academics like Joseph Featherstone and Lillian Weber pioneered the movement, and spent as much as 18 months (in the case of Weber) observing English primary schools. In 1969, study teams from 20 American cities went to England, and in 1971 over 300 articles about the English primary reforms had been written in the USA. The number of free schools grew rapidly during the late 1960s and early 1970s, reaching around 500 by 1972 (Ravitch, 1983).

This type of policy-oriented comparative education, with an emphasis on transferring solutions from one context to another, continues in the present days (Beech, 2006a). However, this chapter suggests that in current times, there are new (or increasingly more powerful) actors in the educational field who are involved in the business of educational transfer. It will also be suggested that, given the involvement of new actors in the field, processes through which knowledge about education moves between contexts has taken specific forms and that, consequently, comparative education needs new theoretical frameworks to try to grasp these processes and their practical effects.

The chapter is divided into three sections. The first section will reflect upon the new configuration of the global educational field. The second part will concentrate on the analysis on international agencies and the way in which they promote certain ideas and practices about education. The third section is the conclusion.

New Kids Strolling Through the Global Garden

The movement of educational ideas, policies and practices from one place to another has been addressed in Comparative Education through the concept of transfer. Interpretations of transfer have been mostly centred on relations between national states (Beech, 2006b). However, under current conditions of ‘globalisation’, foreign influences have become more complex. Giddens refers to a ‘global society’ as a society of ‘indefinite space’ (1994: 107), in which no one is outside, since pre-existing traditions cannot escape having contact with ‘the other’, and with alternative ways of life. In such a context, significant social relations exist which are neither between nor outside states, ‘but simply crosscut state divisions’ (Giddens, 1990: 66–67).

Therefore, in order to analyse foreign influences in education a wider concept of space is needed. Of course, current theories of foreign influences in education should still consider the state as a fundamental actor. However, such theories should also be able to take into account other actors that are involved in processes of transferring ideas about education between contexts, such as international agencies, consultants, universities, corporations, development agencies, regional blocks and NGOs.

For example, ‘charismatic consultants’ travel around the world recommending their solutions and promoting educational change at the school, district and state level. Similarly, universities in many parts of the world have faced (and are still facing) major reform pressures which include the notion that they should find ways to supplement the income that they receive from the government (Cowen, 1996). As Lyotard (1984) noted some time ago, in our times knowledge is produced in order to be sold. So, if

the Department of Education of a given University develops certain knowledge about how to make schools (or districts or national systems) more 'efficient and effective' they should sell this knowledge in the market in order to contribute to the performance of the organisation. Universities have been involved in the business of consultancy for some time. But, like mercantilism that fuelled European imperialism in the search for new markets since the sixteenth century, the current situation in the financing of universities in places such as the UK creates compelling incentives for the 'colonisation' of new markets in which to sell consultancy, especially in the less 'developed' countries. Thus, many universities have created (or strengthened) a special unit for 'international development', and they are becoming powerful players in the game of promoting policy-oriented educational ideas.

The European Union also influences educational policies in its Member States, albeit in a different way. The Treaty of Maastricht established that the principle of subsidiarity is applied to education – the Community's action is only subordinate and supplementary to that of the Member States. Nevertheless, the European Union has done much to orient education policy within its political space at least in three ways. The first way in which the Union influences education policy is by promoting 'co-operation' between its members by suggesting that national education authorities should exchange ideas and learn from the 'best practices' that have been identified in different educational systems within the Union (Nóvoa, 2002). For example, the *European Report on Quality of School Education* claims that its intention is to create a climate for dialogue and 'to provide a strong basis to learn from one another' (Nóvoa, 2002). As Nóvoa notes, these words sound very similar to the rhetoric of the comparativists of the nineteenth century. The Union also gives policy orientations by establishing certain indicators or benchmarks that they suggest (given the principle of subsidiarity) should be followed by national education systems. Finally, the aim to establish a 'European Higher Education Area' through what has become known as the 'Bologna Process' is an example of the third way in which the Union shapes national educational policy within its area of influence. In this case, the Union is explicitly promoting the idea that institutions at the tertiary level across Europe should become more standardised by developing similar structures for their courses, a credit system, comparable degrees, and systems of quality control (Nóvoa, 2002).

Corporations that provide educational services are also becoming powerful players in what they see as a 'global educational market'.¹ In places like the UK, the public sector is outsourcing some of its educational services (ranging from building projects to the running of Local Educational Authorities or the provision of school inspections, in service training for teachers or school meals) to the private sector in what is known as Public-Private Partnerships (Cardini, 2006). Some of the companies that participate in such schemes offer educational consultancy and educational services in several countries. For example, the message from the Chief Executive in the web page of Nord Anglia Education PLC states that:

Nord Anglia has transformed itself in the last year through harnessing the strength of our people and services within the UK and using them to realise overseas growth opportunities. Having recognised the International potential

for our business, we have been building management capacity and operational reach in a number of overseas markets for some years (<http://www.nordanglia.com/chairman.php>)

Global Education Management Systems (GEMS) is another company that has oriented its services to the global market. GEMS operates a ‘growing international network’ of 65 schools spread across 7 countries (the United Arab Emirates, the United Kingdom, India, Qatar, Germany, Libya and Jordan). According to its Chairman:

GEMS is able to develop and manage schools that meet the needs of *any community, anywhere in the world*. . . For over three decades we have provided high quality education to hundreds of thousands of students from around the world. Through ongoing research and continuous innovation, and *an advisory capacity to government agencies, GEMS has become a catalyst for change in the education sector*. (www.gemseducation.com – emphasis added)

The growth of international schools run by multinational corporations raises a series of questions about the possible emergence of a ‘global elite’ and the contribution that these schools could make to its formation (Lauder, 2007). Nevertheless, what is more significant for the analysis offered in this chapter is that these companies are acting as educational advisors to schools and local and national governments around the world. Of course, the operations of these companies cannot be equalled with the imitation of the *Grandes Ecoles* in Brazil (Cowen & Figueiredo, 1992) or with the transfer of the US credit system to Chinese universities (Steiner-Khamsi, 2000). They are different processes. But that is precisely the point I want to make: as new types of actors participate in the ‘business’ of giving policy-oriented advice based on the transfer of ‘solutions’ from one context to another, global educational space becomes more complex, and comparative education as an intellectual field needs to create new conceptual apparatuses in order to understand the circulation of ideas about education in the current world, and how this circulation affects actual educational practices in different contexts.

In order to collaborate with such a project, the next section will offer some reflections about the work of one of the most powerful type of actors in the global educational field – international agencies – and how we could understand the way in which they influence educational policies and practices through their recommendations.

Global Educational Discourse: International Agencies and the Circulation of Knowledge

Organisations such as UNESCO, OECD and the World Bank were created for the reconstruction of Europe after the Second World War (Beech, 2006b). As this function became redundant, in the 1950s and 1960s, the work of these agencies has been aimed at the ‘development’ of the world. It should be kept in mind that this new role of international agencies coincides with a period in the field of comparative education that

was analysed by Cowen as a period in which little theorising occurred: 'That is, what passed as theorizing was the construction of a strong methodological discourse, and methodological schools' (Cowen, 1994: 102). The theme of 'culture' was subordinated to discussions about scientific methods. Thus, 'with the exception of the multicultural issue, culture was not problematized in terms of the political universe' (Cowen, 1994: 102). It was a time when studies of comparative education were dominated by an 'intellectual and political confidence that being a lender was a benign act, and that being a borrower was not too dangerous if money and good consultancy advice was available' (Ibid.). Furthermore, this confidence was reinforced some years later with analyses such as the one offered by Noah and Eckstein in 1969 that defined the initial efforts of international agencies as being in an advanced position in the fictional scale created by their belief in a linear progression towards a scientifically legitimated comparative education: 'The work of these organizations is in the hands of specialists. Thus, what began as philanthropy has ended with professionalism' (Noah & Eckstein, 1969: 82).

At least in Latin America, international agencies promoted developmental and technocratic views about education in the 1950s and 1960s. 'Planning and Development' were the governing words. UNESCO and OEA (*Organización de Estados Americanos*) organised a 'Conference of Ministers of Education' in Lima in 1956, there was an 'Inter-American Seminar of Integral Planning' held in Washington in 1958, and in that same year UNESCO organised the 'Inter-American Conference on Education and Economic and Social Development'. Similarly, in 1964, in Argentina, OECD published a study called 'Education, human resources and economic development' in collaboration with the National Council for Development, which had been established in 1961 (Southwell, 1997).

When they were promoting developmental and technocratic views, international agencies were advocating a number of abstract universal social technologies (such as educational planning) that – in the logic of these agencies – could be used to improve education in most contexts. With the influence of this technical rationality, which introduced social technologies such as 'educational planning' and the notion of 'curriculum', there was a tendency to increase the bureaucracy and division of labour (at least) in Latin American educational systems. In addition, this type of rationality contributed to a division of labour at the international level: international organisations positioned themselves as the 'scientific experts' that can design universal educational solutions. Their proposals were and are legitimised by claims to a scientific status (UNESCO, 1996; Lockheed, 1992). Thus, their recommendations are presented as being 'neutral and objective' (Papadopoulos, 1994), and they can be applied in most contexts to improve education.

The 'transfer' of educational knowledge is currently considered to be one of the main roles of UNESCO, the World Bank and OECD. Since its first loan for education in 1963, the World Bank has become the largest single source of external financing for education in 'developing countries' (World Bank, 1995: 14). However, the Bank acknowledges that its funding still represents only 0.5% of 'developing countries' total spending in education. 'Thus, the World Bank's main contribution must be advice' (1995: 14). This coincides with a new vision that the Bank has of its own role:

[T]o become a Knowledge Bank that spurs the knowledge revolution in developing countries and acts as a global catalyst for creating, sharing, and applying the cutting-edge knowledge necessary for poverty reduction and economic development. (World Bank, Web page, Cited November 2001)

Even though the World Bank expressly embarked in this new vision in 1996, this declaration is rather the recognition of a previous shift in the Bank's roles. The *World Bank Review: Priorities and Strategies for Education* includes amongst its references more than 30 educational texts published by the World Bank before 1996 (World Bank, 1995).

However, it is not only through publications that the World Bank acts as a 'global catalyst' of knowledge. The Bank's lending programmes 'encourage governments to give a higher priority' to certain reforms, or to primary rather than higher education... 'Bank-supported projects... pay greater attention' to particular principles, and they support the involvement in certain practices through emphasis on specific policies (World Bank, 1995: 15).

Thus, when the World Bank declares that its fundamental objective in education is 'helping borrowers reduce poverty and improve living standards...' (1995: xii). The use of the word 'borrowers' here does not only imply the borrowing of funds. Rather, the word 'borrowers' in this statement should also be seen as it has traditionally been used in comparative education: as referring to the borrowing of (particular) ideas. That is, when 'client countries' receive a loan for educational purposes from the World Bank, this act is not only a transfer of funds, but it is also an educational transfer. Together with financial resources, the 'client country' receives a particular vision of education.

The 'transfer' of educational knowledge has always been at the centre of UNESCO's agenda (Mayor, Sema & UNESCO, 1997). As an 'organization for intellectual co-operation', UNESCO does not have a function of 'direct control'. Instead, it 'creates a favourable environment, puts forward ideas, transfers knowledge... and, whenever possible, resources' (UNESCO, 1996: 1).

Similarly, one of the most important objectives of OECD is to search for certain universal values, rules and policies and promote them amongst member and non-member countries. However, the OECD has no prescriptive mandate over its member countries (Papadopoulos, 1994). As part of this role, the OECD 'helps policy-makers adopt strategic orientations... by deciphering emerging issues and identifying policies that work' (OECD, Web page, cited November 2001). In addition, OECD produces 'internationally agreed instruments, decisions and recommendations to promote rules of the game' in certain areas (2001). Thus, the 'transfer' of 'cutting edge' educational knowledge is one of the main self-proclaimed roles of UNESCO, the World Bank and OECD.

Each of these agencies has different proposals for education. The particularity of the educational vision of the World Bank, when compared with the other agencies being analysed, is its strong emphasis on economic issues. From this perspective, educational reform should be oriented towards keeping pace with 'economic structures' (World Bank, 1995: 3). Thus, the first of the two key priorities for education is to 'meet economies' growing demands for adaptable workers...' (1995: 1); and East Asian countries are often used as 'outstanding examples of what can be achieved when the education system is reformed along with the economic system' (1995: 50). Economic inequalities amongst countries are seen in the Bank's work as a direct consequence of educational disparities.

‘For example, if in 1960 the Republic of Korea had had the same low school enrollment rate as Pakistan, its GDP per capita by 1985 would have been 40 percent lower than it actually was’ (1995: 23).

The World Bank’s perspective is strongly based on human capital theory, a theory that – it is claimed – ‘has no genuine rival of equal breadth and rigor’ (1995: 21). The kind of analyses conducted (or published) by the Bank that help to construct its position in education, are generally based on measurements of social rates of return to investment in education. Although the Bank acknowledges that these rates are sometimes difficult to measure, they also note that this kind of analysis has ‘withstood the tests of more than three decades of careful scrutiny’ (1995: 20–21). As a consequence of the Bank’s emphasis on economic matters, most analyses are made in terms of ‘effectiveness’, defined as cost-effectiveness. For example blackboards, chalk and textbooks are considered to be the ‘most effective *instructional materials*’ (1995: 7). Similarly, group work is seen as a promising teaching technique for ‘developing countries’ because it is ‘known to be cost-effective’ (Lockheed, 1992: 64).

UNESCO has a very different concept of development when compared with the World Bank. The vision that equates human development to human resource development is criticised in UNESCO (Mayor, Sema & UNESCO, 1997). Human beings should not be seen as merely the means of production and material prosperity:

It is simply a matter of regarding human beings not as instruments, means to the attainment of economic objectives, but as ends in themselves, the economic objectives being subordinated to their self-fulfilment and well-being. (1997: 89)

UNESCO’s is a humanist perspective, in which the human being is at the very heart of development. From this point of view, education should be directed to ‘the full development of the human personality and to the strengthening of respect for human rights and fundamental freedoms; ... it shall promote understanding, tolerance and friendship among all nations, all racial or religious groups’ (1997: 89–90).

In between UNESCO’s humanist perspective and the World Bank’s emphasis on economic issues lies the educational position of OECD. Papadopoulos (1994) suggests that although economic concerns have dominated OECD’s work, this dominance is ‘tempered by recognition of the social dimension and purposes of economic growth and development’ (1994: 11). Thus, OECD has an ‘inferred role for education, both for the contribution it can make to economic growth and as means by which the purposes of such growth, namely an increase in well-being, can be given reality’ (1994: 11).

Therefore, these agencies have conflicting views on some educational issues and they even engage in explicit controversy (as when UNESCO criticises the World Bank for making teachers the ‘villains’ of the difficulties faced by countries to reduce educational costs) (Carnoy, 1999). Jones and Coleman (2005) reveal the role of politics in the space of multilateral agencies, showing how collaboration, competition, and the demarcation of geographical and intellectual territories have played a significant part in the shaping of international agencies dealing with education. For example, they argue that the famous 1996 report *Learning: The Treasure Within*, prepared by the International Commission on Education and Learning for the Twenty-First Century for UNESCO was

an overt attempt to restore UNESCO's political credibility and fortunes following the debacle of the mid-1980s. With UNESCO's 'lead agency' status in educational development very evidently in decline, threatened by the OECD in the north and the World Bank in the south, the commission was charged with promoting in fresh guise UNESCO's conventional normative concerns.... (1996: 85)

However, although the proposals of UNESCO, the World Bank and OECD are different, a recent study about the influence of these agencies on reforms of teacher education in Argentina and Brazil in the 1990s (Beech, 2005) identified a series of underlying assumptions that were common to the proposals of these organisations between 1985 and 1996, revealing a general system of thought that made these simultaneous and apparently contradictory opinions possible.

An analysis of the assumptions about the future embedded in the work of these three agencies revealed a striking similarity in the way that these agencies read the future as 'the information age'. Furthermore, these agencies not only have a similar reading of the future, but they also promote very similar educational principles that should be used to adapt most educational systems to the information age. Thus, within the educational proposals of these agencies a single universal model of education was identified, rather than three different models (Beech, 2005).

This model is offered as an ideal for most educational contexts. It should be used to judge most educational systems and, then, once the faults have been identified, as a model for reform. In this way international agencies are producing a 'global educational discourse' (Beech, 2005).

This discourse is global because of its spatial scope (it has education in the whole world as its object). It is also a global discourse in the sense that it is a theory that in the name of some 'true' knowledge, and some idea of what constitutes good education offers a universal model of education as a global strategy that could solve most educational problem in most local contexts.

Global educational discourse moved into the Argentine and Brazilian educational systems in the 1990s contributing to an all-embracing reform of each of these educational systems, creating the conditions of possibility for certain educational ideas and practices, while at the same time limiting the possibility for other ways of thinking about education – which is to say, ways of acting – to arise. The ideas and practices that could be included within global educational discourse implied a significant rupture with the kind of education that had been offered in Argentina and in Brazil. For example, international agencies promoted in the 1980s and 1990s an education based on the development of competencies. This type of education is very different from the traditional encyclopaedic definition of knowledge in the Argentine and Brazilian educational systems, where education was very much based on the transmission of facts and information that students should remember. Thus, given these differences, it was not only some aspects of these educational systems that were seen as being inefficient. The view was that the whole system had to be changed, and the model that was followed was the universal model of education for the information age promoted by these agencies, based on the principles of decentralisation, school autonomy, the professionalisation of teachers, a curriculum based on competencies and the setting up of central evaluation systems (Beech, 2005, 2006b).

This abstract universal model is offered as a norm against which the adequacy of existing educational practices in a given context can be measured. By defining the 'problems' in a given educational context, international agencies set the agenda for discussions about how to 'improve' education. Then, once the 'problems' have been identified, there are only a limited number of themes that can be discussed, and a limited number of policy options that can 'solve' these 'problems'. These possible solutions are also offered in the model. Consequently, it is by defining the problems of an educational context and simultaneously offering the solutions to these problems that the model promoted by international agencies narrows the discursive space of possibilities in educational contexts to which it moves.

However, the significant changes seen in the 1990s in Argentina and Brazil at the level of official rhetoric did not necessarily translate into practice. On the contrary, as portrayed by educators who were interviewed, the implementation in Argentina and in Brazil of the universal model of education promoted by international agencies was faced by resistance, reinterpretations and several unexpected practical problems.

Beech (2005) explained the way in which international agencies influence educational reforms by indicating that these agencies were 'producing' a global educational discourse. However, it is not clear where this discourse comes from. Are international agencies reproducing through their proposals a discourse that they produce? Or are international agencies reproducing a broader discourse that is produced somewhere else?

In order to explore these questions international agencies and 'global educational discourse' need to be placed within a general theory of the circulation of discourse in the global educational field. The development of such a theory can be divided into three tasks:

- To identify different positions within the global educational field
- To identify the relations between these different positions or, in other words, to understand how discourse moves between these positions
- To understand how discourse is transformed as it moves between different positions

Bernstein's theory on how different positions of subjects 'within a discourse' affect the way in which these subjects interpret and act upon pedagogic discourse will be adapted to carry out the first of the tasks defined above (Bernstein, 1990). However, for the sake of clarity, Bernstein's vocabulary will be slightly altered and I will refer to 'positions within the field', rather than 'positions within discourse'.

It is important to emphasise that the different positions within the educational field are contexts of production, recontextualisation and/or reproduction of discourse. Individuals can occupy more than one position within the field at the same time, or they can change their positions in the field at different times. Nevertheless, it will be the position within the field that will define the resources and possibilities that the subjects who occupy that position have to engage with and act upon educational discourse (Bernstein, 1990).

Five positions will be identified: global academic space, international agencies, the state, local academic space and educational institutions. Initially each of these positions will be described and later the relations between them will be considered.

Global academic space is the site in which ‘new’ ideas are selectively created and changed, and where specialised academic discourses are developed. This context is created by the positions, relations and practices arising out of the production of what I shall call ‘global academic discourse’. It is at this level that the controls of the thinkable/unthinkable mostly lie:

Today the controls on the ‘unthinkable’ lie essentially, but not wholly, directly or indirectly in the upper reaches of the educational [field], in the part concerned with the production rather than the reproduction of discourse; whereas the ‘thinkable’ is a different power-regulated recontextualizing, in the lower reaches of the educational [field] – that is, in its reproductive rather than in its productive levels (1990: 181). (*The word ‘field’ has been inserted, replacing the word ‘system’ from Bernstein’s quote to adapt it to the language of this chapter.*)

Global academic space is constituted by the flow of ideas through social, academic and political networks. Castells (2000: 408) suggests that there is a new spatial logic in the information age that he labels ‘space of flows’. This spatial form is characteristic of social practices that dominate and shape what he calls the network society. By flows Castells understands the ‘purposeful, repetitive, programmable sequences of exchange and interaction between physically disjointed positions held by social actors in the economic, political and symbolic structures of societies’ (2000: 442). The network of (mainly electronic) communications is the fundamental material support that defines this space. The space of flows is the dominant spatial logic of society because it is the spatial logic of the organisations and institutions which play a strategic role in shaping social practices and social consciousness in society at large. This is the space that is occupied by the ‘technocratic-managerial-financial [and academic] elites’ (2000: 443).

The flow of ideas that constitutes global academic space is materialised through different kinds of material supports, such as international academic journals and books, international conferences, the movement of university staff and students and international research projects.

The people who occupy this position are individuals from different cultures that participate from this exchange of ideas, but in order to participate, these people need to be ‘bilingual’: they have to master both their own culture and a cosmopolitan ‘global academic culture’ that is needed to operate in this site. Even though different cultures contribute to the formation of this ‘global academic culture’, this does not entail that all partners are regarded as equal in the dialogue. Western European and North American cultures are dominant in global academic space.

The second position that has been identified is the position of international agencies. Based on questions of urgent pragmatism and melioristic action, international agencies have positioned themselves as the experts that can interpret ‘global academic discourse’ and translate it (through a process of oversimplification) into practical universal educational proposals.

Thus, international agencies could be seen as a site of reproduction of ‘global academic discourse’. However, as international agencies reproduce this discourse they

base their proposals on a similar set of assumptions. They do not problematise that which is postulated as self-evident. Their concern for questions of urgent pragmatism blinds them from seeing on what kind of assumptions, familiar notions, of established and unexamined ways of thinking their practices are based. In this way, international agencies limit their own discursive space. Thus, as they put forward their proposals, through a process of oversimplification, they are producing a different discourse that has been called in this chapter 'global educational discourse'.

The third position that has been mentioned is the state. Overall, the state is the site of production of a specific type of discourse that I will call 'policy discourse'. Therefore, the state is in a position in which it has to translate other discourses through a process of negotiation into educational policies. Which discourses? That is a fundamental question that would have a different answer in different places at different historical periods. In this sense, the state is the stake of a political battle.

The next position that has been identified is 'local academic space'. This context is created by the positions, relations and practices arising out of the production of 'local academic discourse'. This discourse is partly produced through the interpretation and translation of global academic discourse. However, this position also feeds global academic discourse with the local discourse in a circular relation. In different societies there could be considerable differences in the extent to which this position is developed. Significant particularities in the relations with other positions could also be expected in different places at different times.

Finally – it is being suggested – educational institutions are overall created by the positions, relations and practices arising out of the reproduction of discourses produced in all or some of the other positions. In theory, in most societies, it should be the policy discourse produced by the state that should have the strongest influence on this position. However, in some societies, local academic discourse could have an important influence on institutions. In societies in which universities are engaged in research, a major distinction should be made between types of institutions. In those cases, universities also participate in the production of local academic discourse, and some of them could even participate in the production of global academic discourse. Consequently, the subjects who are positioned within the university have other resources and possibilities to engage with the discourse that they are expected to reproduce.

Now that the different positions have been defined, the most important issues to consider are: the relations that are established between the different positions (or how discourses move between them); and to understand how discourse is transformed as it moves between different positions.

Overall, in the 1980s and 1990s, the movement of global academic discourse to international agencies resulted in a transformation of this discourse through a process of oversimplification into what has been called in this chapter 'global educational discourse'.

When international agencies appropriate certain concepts or ideas they transform them into an oversimplified generalisation that is offered as an educational solution for most contexts. This advocacy is made without specifying context and thus, inevitably, ideas need to be simplified to make them malleable enough to adapt to every context, but at the same time able to retain certain stability. In this way, global educational

discourse is produced. This discourse then becomes especially attractive for some states because of its simplicity (Ball, 1998).

This discourse introduces a language, a way of classifying and thinking about education. These words and concepts construct social reality as much as they express it and mould the way in which education is understood and thought about. An example can be seen in the difficulty to break away from the concept of 'educational systems' or the classification of primary, secondary and tertiary education. These notions have framed the way in which people think about education for many years and in many cases they were disseminated by international agencies (Cowen, 2000).

The concept of 'lifelong learning', like the idea of an 'educational system', was probably not created by an international agency. But that is not the point. The original concept could have been very complex and specific. It is through the process of oversimplification described above, that these notions develop into a part of global educational discourse.

Furthermore, this process of oversimplification is inevitable given the way in which international agencies define social space, mainly dividing the world into developed and developing countries. This way of thinking about social space might be helpful to distribute budgets and decide how much money to 'invest' in each country or region. However, if this definition of space is used for policy diagnosis and for advocating policy it inevitably develops into dangerous generalisations. In other words, if the specific role of international agencies is to capture educational discourse and translate it into policy recommendations that can be applied in most contexts of the world (or a region) it is inevitable that this process will result in the oversimplification and over-generalisation of the original ideas.

This is a dangerous process because, as has been shown for the cases of Argentina and Brazil (Beech, 2005), the effects of localising global educational discourse in practice cannot be predicted. Due to the specific position of international agencies within the educational field, the universal model of education that they promote cannot consider the specific contextual circumstances that affect the way in which policies are interpreted and put into practice (Ball, 2000). Consequently, the practical effects of the appropriation of global educational discourse in an educational system cannot be simply read-off neither from the proposals of international agencies, nor from policy discourse.

On the contrary, it has been shown (Beech, 2005) that there are significant problems in the translation of the abstract simplicities of the universal model of education promoted by international agencies into context-bound interactive practices. Although the model is universal (it does not consider the specificities of each context to which it moves), the way in which the model is adopted and adapted depends on the characteristics of the contexts of reception. Consequently, the main problem is not so much that the 'anticipated' effects are not attained, but rather the unexpected effects that global educational discourse produces as it is localised. Therefore, maybe international agencies should revise their approach that promotes global abstract strategies to solve local specific problems.

The relation between international agencies and the state – and for that matter all of the relations considered in this model – cannot be abstractly analysed. In other

words, the positions in the global educational field that have been mentioned could, in principle, be used to analyse the circulation of discourse between and within different societies. Thus, the relations between different positions will only be analysed in the remaining part of this chapter for Argentina and Brazil in the 1990s.

The question about which discourse was used by the state to produce its policy discourse has a clear answer for Argentina and Brazil in the 1990s: global educational discourse displaced available discourses in the state in both countries (Beech, 2005). Furthermore the process through which global educational discourse was translated into policies did not include a major transformation of this discourse, and no significant differences were perceived between the translations made in the Argentine and the Brazilian states (Beech, 2005).

So what happened with local academic space in Argentina and Brazil? The basic question is how local academic discourse related to the state in Argentina and Brazil in the 1990s. An immediate answer would suggest that there was a blockage between the state and local academic space. Apparently, global educational discourse pervaded the state, leaving no space for local academic discourse. However, the uniformity of themes that can be seen in academic discourse in Argentina and Brazil in the 1980s and 1990s (Beech, 2002) suggests that there was also a very strong connection between global educational discourse and local academic discourse in Argentina and Brazil in the 1990s.

Thus, there seem to be two major problems with local academic space in Argentina and Brazil. The first problem is the extent to which local academic space is developed. The second problem is the extent to which local academic space in these two countries is independent from both the state and from international agencies.

I would like to put forward the argument that what happened in Argentina and in Brazil in the 1990s was that the distinction between these three different positions (international agencies, the state and local academic space) was blurred. Most of the 'elite' academics in Argentina (and at least some of them in Brazil), as they ascend in the academic 'hierarchy', are hired by international agencies and/or by the state. Furthermore, international agencies (and to a certain extent the state) are fundamental sources of research funds in these countries and they define an agenda when offering these funds.

The result of having the same individuals occupying these three different positions is that a class of gatekeepers is developed and discursive space is closed in these three positions. This class of gatekeepers controls the relation of the educational system to global academic space. Since these gatekeepers also control local academic space they control the production of knowledge and, consequently the relation of the educational system with the 'thinkable/unthinkable'.

If international agencies through global educational discourse close discursive space in the state and in local academic space it is very difficult for alternative ways of thinking about education to develop. In theory, it should be local academic space that should produce an alternative to global educational discourse and compete with international agencies, trying to occupy the discursive space of the state. However, this has not happened in Argentina and in Brazil in the 1990s.

Finally, the application of the model to Argentina and Brazil in the 1990s showed a significant disconnection between global educational discourse (and policy discourse) and educational institutions. At this level global educational discourse was

significantly transformed as it met local discourses and context-specific circumstances. This transformation resulted in resistance, reinterpretations and several unexpected effects.

An example of this can be seen in the practical effects of the reform of curricular regulations in Argentina. Before the reforms of the 1990s, teachers in Argentina were not expected to have any participation in decisions related to the contents they had to transmit (Gvirtz & Beech, 2004). Influenced by international agencies, the reform emphasised autonomy and creativity on the side of teachers who should be able to have freedom to choose the specific contents of the lessons according to local context and students' characteristics, but respecting general guidelines from the central agencies of the state. However, a series of interviews with teachers and teacher educators showed that many Argentine teachers, as they were faced with an autonomy for which they were not prepared, started using the indexes of the manuals that publishing companies produce for students to structure their lessons (Beech, 2005). Since the new curricular documents do not provide a detailed guide to which contents should be included, (some) teachers looked for another guide that could replace the prescriptive curriculum which they had in the past. They found this guide in the manuals that editing companies produce for students. Therefore, an idea that is acceptable as an abstract ideal (that teachers should have autonomy to decide on the contents of lessons) results in unexpected consequences as it is localised in practice and recontextualised.

Furthermore, the consequences of similar policies were very different in different contexts. For example, international agencies promoted that practice-based training in schools should become a major part of the training of teachers. This idea, that was adopted both in Argentine and Brazilian policies for teacher education, had very different interpretations in each of these countries. In Brazil, dominant conceptions of teacher education included the idea that future teachers should experiment with real classes, constructing their own pedagogic knowledge. Consequently, trainees already spent a great part of time in practice-based activities, and therefore teacher educators who were interviewed considered the extension of time spent in these activities as '*delirious*' and impossible to administer. In Argentina, from the perspective of teacher educators, trainees spent very little time in practice-based training and, therefore, the extension of time spent by trainees in schools was seen as a positive aspect of the reform and as a response to a historical demand of teacher educators (Beech, 2005). As this abstract proposal of international agencies was localized in different contexts the practical effects were very different in each of these specific localities.

Thus, although international agencies make universal proposals that, in theory, are applicable to almost every context, the practical effects of these proposals depend very much on the specific characteristics of the contexts in which they have to be translated into interactive and sustainable practices. In the end, these processes result in a strong disconnection between global educational discourse (and policy discourse) and educational institutions.

Considering the uniformity in educational reforms and in local academic discourse in Latin America it seems as though these overall results could be generalised for many countries in Latin America. However, the model should be tested in these societies. In the concluding remarks, some ideas about how the model could be further developed will be opened up.

Conclusion

It has been suggested in this chapter that global educational space has become more complex, with different types of actors that are increasingly participating in the business of providing policy-oriented advice to governments, based on the transfer of educational ideas or practices from one context to another.

Then, the chapter has concentrated on one specific type of actor: international agencies. A theoretical model was offered, suggesting that the internal logic of international agencies provided these institutions with certain resources and possibilities to engage with and act upon educational discourse. It is important to emphasise (again) that the model analysed international agencies as a given position in the global educational field. Individuals who work for the agencies can occupy at the same time other positions, such as local academic space if they do research in the university or in research centres. Nevertheless, although the resources of the individuals are important, the position they occupy in a specific moment will also have an influence on the possibilities that a given individual has to engage with educational discourse. For example an academic who does research in the university might take 3 years since the moment she starts to design a research project until the moment she publishes her findings in a book. If that same person is then hired by an international agency to undertake a study about, say, inequities in schools, she might be asked to do the field work, to analyse the data and to provide the organisation with a report that is 'relevant to practice' in 1 year. Clearly her own training as a researcher will influence the type of knowledge she produces in both cases, but it is also quite evident that the possibilities she had to engage with educational discourse in one case and in the other is very different, resulting in two texts, produced by the same person, that offer very different types of discourses. Then, of course, with the pressures that academics have to generate income for their institutions and/or for themselves through contract research, the logic of basic research and of academic space might be changing (see for example Ball, 2001).

Nevertheless, returning to the main argument of this paper, the question is whether the other actors that have been mentioned as active participants in the global educational field (corporations, the EU, ONGs, consultants) could be included in the model that has been offered. In order to include these types of actors as specific positions in the global educational field it is necessary to identify an internal logic from which certain regularities in the resources and possibilities they have to engage with and act upon educational discourse could be deduced. So, maybe the profit-making logic of corporations affects the way in which these organisations promote certain educational practices, and although there are many different types of corporations engaged in the business of promoting educational ideas and practices, some regularities could be found in the way in which corporations transform educational discourse into recommendations for governments and institutions. Similarly, if applying this model to European space, the European Union should be added as a major position. The internal logic of the EU as a position in the global educational field cannot be directly deduced from the logic of international agencies that has been identified in this chapter. The EU probably has its own logic and specific resources and possibilities to engage with and act upon educational discourse.

The other issue to consider is recontextualisation, or how is educational discourse transformed as it moves into different positions. We need to understand how institutions transform the abstract recommendations of other actors into interactive and sustainable practices. It is at the level of schools, teacher-training colleges, universities and other practice-based institutions that the practical effects of the circulation of discourse in the global educational field can be seen. Probably, as Sadler noted, the gathered cuttings will not transform into a ‘living plant’ when they are implanted in a new soil, but that doesn’t mean that there are no effects. Even a dead plant carries micro organisms that can alter an ecosystem, and as comparativists we need to understand how the new kids strolling through the global garden are affecting ours.

Notes

1. The following reflections about the involvement of corporations in the global educational market have been inspired by Stephen Ball’s seminar ‘La participación del sector privado en la educación pública’. Organised by the British Council in November 2005 in Buenos Aires.

MOBILITY, MIGRATION AND MINORITIES IN EDUCATION

Noah W. Sobe and Melissa G. Fischer

In recent years space and spatiality have increasingly become seen as important research topics in comparative and international education. By taking an interest in space as a domain of cultural practice, the researcher can also bring into resolution the restrictions on movement, inducements to movement, and the related boundaries, flows, and enclosures that have profound impact on the ways that educational policy and schooling practices are implemented, reformed, and contested. This chapter provides an introduction to several global educational issues that benefit from being analyzed in terms of spatial practices. We propose that comparative and international education researchers should be very interested in the ways that space and movement are “problematized,” or, put differently, seen as “problems” meriting political as well as social science attention. This in and of itself has considerable influence on the ways schools are researched globally and on the ways in which educational reforms are envisioned and implemented. Conceptualizations of space and movement also play a key role in the ways that particular groups/“kinds” of individuals are differentially affected by and differentially experience schooling institutions. The present chapter begins by discussing the interest in spatiality that has appeared across multiple academic disciplines. It then moves on to discuss student mobility and the education of migrant students as two specific educational issues that benefit from being analyzed in spatial terms. In the conclusion we suggest additional topics and areas in which the concepts being discussed here can be fruitfully employed by researchers in comparative and international education.

Space in Historical and Contemporary Perspective

Since the 1970s scholars in a range of disciplines have placed questions connected with space and spatiality increasingly at the center of their analyses (e.g. Cosgrove, 1998; Gupta & Ferguson, 1997; Poovey, 1995; Soja, 1996). Henri Lefebvre’s work (1991) and his suggestion that space be understood as a social production frequently provides a baseline for the argument that a “spatial dimension” is critical for comprehensive understandings of social formations, identities and, indeed, the practices of everyday life (de Certeau, 1984). This trend in scholarship has even led to notions of a “spatial turn” akin to the assertion of a “cultural turn” and “linguistic turn”. Paul Gilroy’s

(1993) work on the “Black Atlantic” stands as a superb example of the usefulness of thinking about space in social and cultural terms, rather than exclusively relying upon natural and territorial criteria. This current has had an increasing presence in comparative and international education scholarship, expressly in the social cartographic work of the late Roland Paulston (1997, 2000) and as a perspective and instrument put to use by a number of scholars (e.g. Beech, 2002; Dussel et al., 2000; English, 2004; Epstein, 2006; Gordon & Lahelma, 1996; Ninnes & Burnett, 2003; Nóvoa & Lawn, 2002). However, the importance that some scholars now give to issues of spatiality should not be seen merely as academic vogue or, alternatively, simply as a progressive improvement in the practices of scholarship. Rather, it is important to set this in the context of main currents in European and American thought which, particularly since the Enlightenment, have exhibited a tendency to view space in temporal terms.

The temporalization of space enabled Europeans who traveled around the globe from the seventeenth century onwards to view themselves as “time travellers” whose journeys allowed them to observe different stages of civilizational progress (Leed, 1991). In indigenous/aboriginal peoples it was possible to see ancient Greeks, Romans, and barbarians (Sayre, 1997). And, accordingly, it was also possible to deploy the temporal category “primitive” as a descriptor of certain groups and their manners and mores. The self-privileging, tautological, and linear evolutionary trajectory that this inscribed is so familiar that it hardly bears mention, except that the pattern of positioning minority and marginalized groups in spaces that could be characterized by an absence of norms of civility and a need for “development” continues up through the present day (Popkewitz, 1998). However, to emphasize that philosophical, historical, and social scientific thought as shaped by the European Enlightenment tends to prioritize time over space is not to deny the historical importance that space has actually had. Over this same time-span, and well beyond the ways it functioned in narratives of progress, spatiality has had profound importance as a strategy of government (with “government” to be understood in this chapter not as synonymous with state but in the broader, classical political theory sense as a category encompassing the minute and multiple ways in which individuals are regulated and self-regulate.)

Nikolas Rose (1999) proposes that since the early nineteenth century we have seen the spatialization of governmental thought along three noteworthy axes. First, one can look at territorializations, the demarcations of spaces such as a “national economy,” “population,” as well as “classroom,” “school,” “family,” and “community.” Once these objects are thought of as discrete spaces it becomes possible to administer them, and to prevent and foster the movement (conceptual or physical) of certain individuals into or across them. Second, one can point to the inscription of power relations through maps, surveys, charts, and tables as “spatializing the gaze of the governors” (p. 36). This captures the importance to government of rendering visible the acts, dispositions, and “being” of those who are its subjects and objects. James Kay-Shuttleworth’s (1832/1970) study of the Manchester poor is an excellent example of how statistical investigations make objects visible so that they can be manipulated (e.g. the construct of “living conditions” as an aggregation of individual experience). Norms and values are inscribed in the very ways that such objects *are seen* as problems that can be alleviated or managed. Third, one can look at the way the “texture” of space has been understood or “modeled” in relation to government. Conceptualized as isotropic (everywhere the same), space

lends itself to repetitive action, reproducible products, standardization, and uniformity (Poovey, 1995). However, in modernity space has also at times been conceptualized to possess thickness and depth, notably in the division often taken to separate human experiences from “underlying” laws and principles (Foucault, 1971; Rose, 1999). When space is conceptualized not as a smooth plane but as nonregular, with varying, uneven depths, principles of differentiation ensue. For example, some areas emerge as sites suited for liberal, democratic participatory politics; others emerge as more appropriately governed through force, authority, and the inculcation of habit. Notwithstanding the fact that “smooth” and “uneven” notions of space produce very different strategies of governance, they can be deployed simultaneously, to be applied to one or another dimension of the social phenomena and kinds of individuals at hand.

Understanding the ways space has served as an arena and tool of modern governance allows us to see the school (1) as an enclosure used in the administration of populations and (2) as a site for the qualification/disqualification of individuals (and specific groups of individuals) for participation/non-participation in other social spaces. As will be seen below, forms of mobility and practices of migration interact with the operations of schooling and are problematized in educational policy and research in ways that are of deep significance for minority and marginalized groups.

Mobility

Closely tied to the social production of space is the social production of movement. Scholarly interest in people and objects in “flux” has exploded in the past two decades. With this, debate has ensued on how to approach mobility and movement as sometimes a privileged condition and sometimes (perhaps even frequently) more of a generic, widespread human experience. As James Clifford (1997) has pointed out, the customary paradigm has been to attribute movement and the advantages that accrue from an ability to occupy multiple positions to cultural elites, academic researchers among them (cf., Riles, 2000). Settlement, stability, and all that remains in-situ (i.e., most of what falls under the much-critiqued classical anthropological notion of culture as static entity) is then coded as a “backwards” provincial remainder needing to be reformed/transformed by “forces” seen as “moving in” from the outside. Connected to this is the analytic and cultural paradigm that views “authentic” forms of mobility as inhering exclusively in the free (and freeing) movements of subjects for whom journeys/departures are a matter of choice. When movement is prompted by economic necessities or forces “beyond one’s control”, it is taken as a considerably less desirable form of mobility (Bartkowski, 1995). This bifurcation is directly reflected in contemporary educational research literature, as is starkly evidenced by the radically different studies that one finds catalogued under the descriptor “student mobility”.

Looking globally and comparatively across education research on “student mobility” exposes a deep contradiction: in some settings this is a cherished objective and key desideratum of educational policy; in others it is woeful problem to be stemmed and urgently managed. In fact, it is quite rare to find any middle ground between the valorizing and excoriating perspectives. There is “student mobility” as exemplified by European Union

(EU) initiatives such as ERASMUS, SOCRATES, and TEMPUS. And, there is “student mobility” epitomized in a United States “school report card” – one of the accountability-related procedures required as part of President George Bush’s 2001 “No Child Left Behind” (NCLB) education reform legislation. In this second case, the reference is to the number of students who enter or leave a school during a given school year, something held to be one of several key indicators of a school’s student characteristics and a plausible mitigating factor in the quest to meet accountability-related performance objectives (Offenberg, 2004). While they diverge sharply, these two uses of the concept of “student mobility” illustrate how the spatialization of education is linked to strategies of governance that inscribe social norms and regulative ideals through the administration of spaces together with those who are (and those who are not) to pass through and across them.

António Nóvoa (2002) argues that mobility has emerged as a key touchstone in EU-oriented European identity formation. The concept becomes a means to imagine European citizenship, as it “contain[s] an imaginary of past journeys and cultural travels [and] suggests a sense of freedom and openness towards the future” (p. 146). EU-mobility programs such as ERASMUS play a symbolic role in inscribing “an experience of Europe in each citizen” (p. 147) that is collectivizing and unifying while also being entirely compatible with an imagined Europe of diversity, multiple identities and complexity. In 2007 the ERASMUS program celebrated its 20th anniversary, having provided grant support that to date has enabled around 1.5 million European university students to study at other institutions within Europe. The program has now been folded into the EU’s new lifelong learning program and will continue at least through 2013. In addition to boosting mobility, transparency, and facilitating the transfer of credits, the ERASMUS objectives include reinforcing the “European dimension” of higher education. As Nóvoa suggests, the program also reinforces the “European dimension” of Europeans themselves. As a technique for producing a collective identity, travel is a classic technique in the national imaginary repertoire (Sobe, 2006; Vari, 2006). Yet, as the EU pursues traditional nation-building strategies (flag/anthem/textbook) in conjunction with a knowledge- and competencies-based strategy that lays out new territories of affiliation and ideals of “Europeanness” (Schissler & Soysal, 2005; Soysal, 2002), mobility and movement have been recast to emphasize participation in networks that bring people together in contingent assemblages and temporary “common” projects (Papatsiba, 2006; Reed-Danahay, 2003). Student mobility in this milieu can be viewed as an individualizing educational practice that places new responsibilities on individuals and centers on employability-related competencies, even as these competencies are revised to encompass civic and political rationalities (Papatsiba, 2005). The TEMPUS mobility program, which targets higher education mobility between the EU and partner countries in Eastern Europe, the Balkans, the Middle East, and North Africa, extends this project of modernization and mutual learning, arguably helping to further cement the linkage between mobility and a European social imaginary configured around participation. This is hardly to suggest that TEMPUS programs don’t produce forms of exclusion (Lawson et al., 2003; Walsh et al., 2005), but rather to emphasize the ways that “student mobility” as it presently appears as an education policy problem in Europe is connected with identity work that normalizes individual movement, flexibility, and multicultural resourcefulness as the proper qualities of the enfranchised citizen.

Standing in stark contrast is the “student mobility” that appears as an education policy problem in the United States. This form of mobility – students moving from one educational institution to another mid-school year – is a particularly common problem in urban areas, though it has been noted as an issue that rural areas face as well (Schafft, 2005). It is quite revealing of ways that student movement is socially coded and culturally constructed in the US context that the policy and research language sometimes shifts from speaking in terms of “mobility” to discussing this as a form of “transiency”, the latter being closely linked with poverty and the perception that the individual(s) in question exhibit an almost pathological inability to live a proper, settled life. In other words, mobility is not seen as an advantage but as an obstacle to progress and stability. We can identify a similarly divergent coding of movement in the distinction sometimes made between “exile” and “refugee” (Clifford, 1997). Although there are great similarities in that both have been somehow forced to emigrate from a country of origin, the “exile” tends to be viewed as an autonomous agent, whereas the “refugee” is frequently stigmatized in terms of dependency (Mosselson, 2007). As mentioned earlier, the 2001 NCLB legislation has brought renewed attention to “student mobility” since this has now become one of the key characteristics that defines a school. Mobility here is related to the spatialization of family and community as objects of government, with Latino populations featuring as a particular concern, something we will also see in the following section on the education of migrant students. Student mobility in this problematization is multifaceted and could, for example, connect with homelessness, foster care, child custody issues, etc. Of course, it should not be overlooked that mobility can also be school-initiated due to discipline policy or the management of overcrowding. Russell Rumberger (2003) argues that while residential relocation is the largest factor prompting US primary and secondary students to enter or leave a school while the school year is in session (typically accounting for around 60% of student mobility) it is far from the sole reason. Particularly given that a large portion of residential relocation is local and would not necessarily force school relocation, some researchers are beginning to argue that student mobility also needs to be viewed as a purposeful, strategic action on the part of students and families who may be changing schools because of their own concerns about safety, teacher quality, and academic opportunities (Kerbow et al., 2003). However, as an NCLB school report card item, “student mobility” serves as an indicator of deviance within a school population, namely the deviance of those who stubbornly refuse to stay within the space(s) that are supposed to confine, regulate and advance them.

These starkly different orientations taken towards “student mobility” are partly – but not fully – explained by the differences in educational levels being considered. To be sure, there are European educational researchers concerned about connections between primary school student mobility and achievement (Demie et al., 2005; Strand & Demie, 2006), just as there are US researchers interested in student mobility in post-secondary education. However, in the US at the post-secondary level, by and large, the overall problematization does not shift from what we have seen at primary and secondary levels: student mobility becomes “multiple institution attendance” and is seen as a complicating factor, typically with adverse effects on degree completion and sector-wide efficiency (Pusser & Turner, 2004). Study-abroad at the college and university level would seem to

be the exception, except that in the US this is much more frequently constructed as an issue of “international exchange” than one of “student mobility”. Obviously studying abroad necessarily requires movement and travel on the part of students, nonetheless it seems quite evident that, in the US, the mobility aspect of this is not inscribed in a social salvation narrative anyway near to the extent that it is in European higher education reform discourses.

A similar contrast emerges when one compares European and US discourses on “teacher mobility”. Professional mobility, including teacher mobility is a policy desideratum only slowly beginning to be realized in Europe (Sayer, 2006). In US contexts this tends to be seen in terms of workforce attrition and through an equity lens that frequently reveals qualified teachers leaving urban schools with high minority student populations (Elfers et al., 2006; Scafidi et al., 2007). To an extent, focusing on different meanings imputed to “mobility” as a research descriptor forces a false dichotomy. Teacher credentials mobility is, after all, very much an active concern in the US. Likewise, teacher attrition and urban teacher retention are very much pressing concerns in Europe. Yet, our hope is that the comparisons drawn in this section usefully expose the conflicted nature of the educational politics around “movement” – as something possessing “proper” and “improper” forms. The regulation of who is and who isn’t to be mobile is a key dimension of the spatial practices within which and by which modern schooling operates.

Migration

It is now canonical in comparative education literature to note that population flows are transforming the composition of social and political communities around the globe. With this come new cultural formations (Appadurai, 1990, 2000) and new educational pressures (Burbules & Torres, 2000; Suárez-Orozco, 2001). This section of the chapter examines migration as a subset of mobility that concerns the relocation of people from one locality to another. Academic researchers and public policymakers frequently find it useful, if not necessary, to distinguish between “voluntary” and “forced” migration. While this distinction is redolent of the cultural coding of different styles of human movement as discussed above (and while some analysis in this vein would seem to be called for), military conflict and war are increasingly pushing issues connected with de facto forced migration onto educational research agendas (Burde, 2005; Pinson & Arnot, 2007; Talbot, 2005) and compelling scholars to confront the legitimately unique combinations of problems (repatriation, restitution, reconciliation, rehabilitation, etc.) faced by those forced to migrate under such circumstances. The discussion of migration that follows in this section will focus only on the category of “voluntary migration” and its frequent association with economic/employment driven relocation. Rather than tackling the enormous topic of immigration and the education of immigrant students (for an excellent synthetic treatment of immigrant education in the US see Olneck, 2004) we will continue with our focus on space and movement and look specifically at the education of migrant students. These are students considered by school authorities to be “in transit” (even while students themselves may have different

understandings of their school attendance). Some basic configurations and contours of migrant education can be illuminated by looking briefly at several cases: China, Spain, the United States, the United Kingdom, and India.

What is sometimes referred to as China's migrant rural population consists of individuals and families from the countryside who have become "unofficial" urban residents, typically because they were drawn to China's eastern urban conglomerations for jobs in the service and industrial sectors. Because of China's Residence Registration System, the children of these internal migrants are not categorized as local residents and until recently have not had access to publicly funded state schools (Liang & Chen, 2007; Shaoqing & Shouli, 2004; Yan, 2005). As a consequence, special unlicensed, private schools for migrant children have sprung up in the last decade – frequently started by migrant workers themselves (Jianhua, 2006; Kwong, 2004). Since 2003, however, government policy has begun to change, and more and more migrant children are entering public urban schools (Yuankai, 2006). In connection with this policy shift, in 2006 over 100 private schools for migrant children were forcibly closed in Beijing. There appears to be considerable variability from city to city as to whether there is adequate capacity in the public schools that are now, in principle, open to the children of China's internal migrants (French, 2007). The number of school-aged children in question is sometimes estimated to be around 20 million and the Chinese case stands as a powerful example of the ways that schooling is drawn into larger politics of social regulation, with considerable consequence for great numbers of children whose social exclusion is further exacerbated by the denial of educational opportunity.

In the United States, since the 1982 *Plyler v. Doe* Supreme Court decision, the equal protection clause of the constitution has been held to grant to the children of illegal aliens the right to a free, public education. Though not all migrant students in the US are of "undocumented status," this decision was pivotal in regularizing the provision of education to migrant students. The federal-level Department of Education contains an Office of Migrant Education that organizes regional networks and administers several funding programs. Alongside this, it is worth mentioning that the US possesses extensive networks of researchers and educators attempting to address the special educational needs of migrant students (Garza et al., 2004; Green, 2003). While the children that fall into this group share certain experiences of mobility as "children of the road," and while many of them are of Mexican descent, this population also includes students from Haiti, Puerto Rico, Africa, Vietnam, Cambodia, and Eastern Europe (Branz-Spall et al., 2003). They face similar challenges in the US school system including segregation due to limited English proficiency and/or their status as migrants; a general inconsistency in educational opportunities (Brunn, 1999); and, home-school conflicts (Lopez, 1999). Despite the attention paid to migrant education, as mentioned, only a small percentage of US educators serving this population have ever received professional development for teaching migrant students. In diametric contrast to the Chinese case, the parents of these migrant students are typically pursuing agricultural labor in rural areas. Nonetheless, a politics of documentation and registration is common to both instances, once again highlighting the school as a site where the regulation of movement is tied to the creation of governable populations.

In the last several decades Spain has experienced a rapid reversal, moving from being an immigrant-producing to immigrant-receiving country. At present around 9% of the population is classified as foreign, with the number of children between the ages of 0 and 14 in this category more than doubling between 2002 and 2006. Data indicate that the pool of foreigners residing in Spain contains sharply diverging profiles. No longer are the majority of Spain's foreign workers from North Africa. Even though Morocco provides the single largest national contingent, as a region it is Latin America followed by Eastern Europe now supplying the greatest numbers (Isusi & Corral, 2007). A sizeable population of Europeans from EU countries has also begun to take up residency in Spain, adding further uncertainty to the pattern or long-term trend that this is all pointing to. It is even unclear what portion of these populations might come to be referred to as "migrant," and what portion "immigrant." Educators face the challenge of teaching heterogeneous classes that include limited Spanish proficiency students (Harry, 2005). Some researchers emphasize that in the face of this Spain has adopted an "intercultural approach" that aims to recognize, accept and value the different cultural groups in Spanish schools (Garcia & Molina, 2001; Santos, 1999). The different ways that these various migrant groups will interact with the Spanish school system remains to be seen. However, when set alongside China and the US, Spain serves as a useful reminder that the spatial politics of migrant education are not fixed to a uniform pattern. The configuration of individuals, institutions, and proper/improper movement across and between is always to an extent in formation.

In the United Kingdom, "traveler" children have been a longstanding concern of educators (Bhopal et al., 2000). The recent post-communist migration of Romani groups out of Eastern and South-eastern Europe has added new layers of complexity to the multiple, and quite different, social/ethnic groups which are sometimes labeled as "gypsy." In the UK in particular, there is an extraordinary diversity within "traveler" communities, some mobile and others settled though still experiencing the social stigma of being considered itinerant (Acton, 2006). Recent scholarship (Derrington & Kendall, 2004) has detailed the continued obstacles that traveler/gypsy children face in schools, though also acknowledging the educational successes and advances that have been made. Among sections of these populations that are in fact migrant, researchers Martin Levinson and Andrew Sparkes (2005) have found that students face problems adapting to the way that space is used within the school, specifically "the highly structured use of space" (p. 764) which generates a cultural dissonance. This mismatch undermines the policy objective of preparing these children for participation in the larger society at the same time as recognizing home culture(s) and enabling these populations to continue to remain somewhat apart. The UK case shows how cross-cultural interaction adds a layer of complexity to the education of migrant students particularly as educators and policymakers sensitive to multicultural education concerns strive to accommodate the cultural distinctiveness of a given migrant population while also affording academic opportunities and attempting to alleviate social exclusion.

Pastoral nomads in Western India constitute one of the country's most marginalized groups (Dyer, 2001). Until quite recently schooling options have been quite limited for the Rabaris, a group in the province of Gujarat whose migratory pastoral practices have been steadily disrupted by development initiatives. For nomadic peoples, formal

education has frequently featured as a centerpiece of state-initiated sedentarization campaigns (cf. Steiner-Khamsi & Stolpe, 2006). However, schooling is also something that can be leveraged by migrant groups to their own advantage. Researcher Caroline Dyer (2001) argues that educational attainment, while uneven, is increasingly viewed as a route to building social capital. Literacy in particular is viewed as standing to “eliminate the current disempowering dependency on others to provide information” (p. 319). Nomadic families frequently place a son in school as a form of “insurance,” less to aid pastoralism than to establish alternative economic options. This particular instance of nomadic migrant education is not a general example that would hold consistent across all instances of pastoral nomadism – such as in Iran or Nigeria (Umar & Tahir, 2000) – but it does illustrate the agency of migrant peoples with regard to education and with regard to their own mobility, even in the face of substantial state-related limitations and restrictions.

The five cases discussed in this section all show the various ways that the spatial enclosures of schools produce or limit participation in other social spaces. As we saw earlier with “student mobility” there is no one experience of educational space and movement but multiple forms of “migrant education” that need to be contextually and historically understood.

Conclusion

This chapter’s discussion of mobility, migrants, and minorities in education has revealed that alongside an interest in the spatial dimensions *within which* schools and education policies operate, it is also necessary to take into account the spatial practices *by which* they operate. In terms of the former, one can think of labor market flows, international trade in educational services, and the new media transmission of youth cultures as phenomena significantly responsible for shaping the “terrain” and “territory” of education. In terms of the latter, it is useful to remind ourselves that at least since the early nineteenth century schools have been a central node in the project of rendering individuals and populations subject to calculation and administration. The creation of spaces that can be studied, evaluated, and managed is one the chief techniques of this form of governance. Though the ways in which various components have been put into relation with one another has experienced considerable change in the intervening two centuries, education policy still fundamentally relies on the production of governable spaces such as “classroom,” “school,” “family,” and “community.” Even a multicultural educational project that attempts to recognize and value gypsy culture or preserve the livelihood of pastoral nomads invariably relies upon such governable spaces. We have proposed that spatial practices need to be analyzed in conjunction with the flows and stoppages that hasten and restrict the movements of people and objects into and across particular spaces. This could be a useful frame from which to analyze what is sometimes referred to as educational borrowing and lending and to use in more extensive and fine-grained studies of immigrant education globally. It also makes an extremely productive ground for cross-cultural comparison of curricular and pedagogical practices.

This chapter has suggested that increased attention be paid to the spatial organization of schooling, whether this is in relation to the physical architecture of classrooms and corridors, or whether this is considered in terms of the space of particular “populations”. Popkewitz and Lindblad (2000) recommend that we approach the issue of educational inclusion and exclusion as involving both a problematic of knowledge and an equity-participation problematic. The latter describes a problematization that takes as its central concern the access and representation of individuals and groups in educational and other social practices and emphasizes the structural role of the state as an interest-driven actor. The former focuses on the systems of reasoning and cultural practices that qualify and disqualify as they establish what is proper and improper or virtuous and deficient. To join these two problematics is a formidable analytic challenge; however, we propose that looking at the spatial practices within which and by which schools operate is one productive way to undertake such a project. It is an avenue of inquiry that promises to be extremely fruitful for scholars in comparative and international education.

FUNDAMENTALISMS AND SECULARISMS: EDUCATION AND *LA LONGUE DURÉE*

David Coulby

Trend Spotting and *La Longue Durée*

An overview of educational discourse, especially in the UK, might review current trends, the latest, fashionable moves in writing on education policy at its various levels: the strands of the discursive strategy of educational policy. Thus, in the last 15 years of educational publication in the UK and in the *World Yearbooks of Education*, there has been writing on education and transitions, the control of the teaching profession, education and post-modernity, education and globalisation.

Some of this writing is spotting trends, ideally at an international level, internal to education: the regulation and de-professionalisation of the teaching profession; the shift to a shorter first degree; a concern at all levels with standards. Another strand seeks to identify wider social trends, such as the transitions in Eastern Europe and the former Soviet Union following 1989 and 1991 (Coulby et al., 2000) or the economic process of globalisation (Coulby & Zambeta, 2005), and to analyse the ways in which they impact on education, or indeed are impacted on by education. Again the perspective of this strand is beyond one state and the systems examined within it may be quite other than that within which the analyst works. An even more ambitious strand seeks to isolate philosophical shifts either within academe or beyond and to show how these either help to understand the role of educational institutions or influence the ways in which they are shaped. Whilst the writing on post-modernity and education might be the most obvious example here, this strand would also include earlier Marxist writing and those concerned with the impact of ‘values’ on education and of education on ‘values’ (Cairns et al., 2001). This trend-spotting aspect of the educational literature is particularly prominent among those writing in comparative or international education. This is appropriately the case since such analysts are well placed to spot the ways in which similar concerns, policies and structures are emerging in different states: the shift to more vocational subjects at secondary school level, the growth of English as the first foreign language, the charging of fees for university education. Moreover, ideally, comparative and international commentators will be well placed to pick up the social and philosophical trends which are emerging within and beyond their state of location and to relate these to educational policy.

As indicated by the citations above, the *World Yearbooks of Education* over the last 10 years exemplify this mode of discourse. Their titles are likely to identify a social

or philosophical abstraction – interculturalism, special needs, urbanisation – and to link this to current and emergent practice in education. This is the normal science of comparative education. The comparative educationist must be alert to, on the one hand, trends in policy and practice in a range of states and, on the other, to changes in the theorisation of the social sciences as a whole. The task then gets to be to provide an exemplified and ever-current set of links between the two. Lo and behold: *Postmodernity and European Education Systems* (Coulby & Jones, 1995).

The job of the comparative and international commentator has, over the last 3 decades, become more complex as governments have set themselves up as instant comparative educationists. The literature and research has in some ways contributed to this, especially the performance league tables beloved of journalists. Technical education is best in Germany, the Fins are best at teaching literacy, Mathematics is best in Taiwan (or was it Hungary?). Politicians and bureaucrats scuttle to Heathrow and Narita in search of instant solutions. Thus one of the trends which comparative and international commentators have needed to chart has been the idiot cultural borrowing brought about by the existence of comparative data and research itself. If it works in Taiwan then obviously it is bound to work in North Rhine Westphalia.

This chapter is not advocating a paradigm shift in comparative and international education discourse. Rather it will make a contrast between this trend-spotting trend (as it were) and another approach to understanding social phenomena.

The French historian Braudel and his followers, along with others working in, particularly, economic history and the history of technology, have sought to understand the long-term shifts in social phenomenon (Braudel, 1985a, b, c, 1989, 1990, 1992). The question, to take an example that irked Braudel himself, is not who won the battle of Waterloo? But rather, how, in the period from the Reformation to 1815, demographically and historically insignificant England (later UK) developed the industrial and military capacity to snatch world domination from the apparently economically and intellectually superior France?

The long processes of history might be exemplified as the spread of Islam across Asia, Africa and parts of Europe; the process of European colonisation and decolonisation; the persistence of the Japanese and Chinese empires; the emergence of North America from scattered settler societies to the current position of the USA; the impact of Latin American mineral wealth, especially Peruvian silver, on the sudden rapid take off of the world economy following Spanish imperialism. At its most extreme, human history can be seen as the agency which spread the plant, wheat, across the surface of the globe (Fernandez-Armesto, 2001). These movements of history Braudel refers to as *la longue durée*.

It is possible across the *longue durée* to identify forces which are operant on a wide range of social phenomena not least on the curricula of schools and madrassas. The ebb and flow of languages across the globe and its educational institutions over the last two and a half millennia may provide an illustration here: Greek, Latin, Arabic, Chinese, Turkish, Spanish and English. The first point to make about this illustration is that these shifts hardly result from the decisions of educational policy makers. They are the result of much longer-term economic, cultural and political forces. Secondly, these changes would not necessarily have been prominent to contemporary trend-spotters. Even the most triumphalistic Roman, as late as the Battle of Actium, would have been unlikely to

predict that Latin would become an international language in Europe and beyond for the next millennium and a half. (Though, when asked what was the most important event of the nineteenth century, Bismarck brilliantly remarked the decision of the US government to make English its official language.) For those less prescient than Bismarck, however, there may actually be a conflict between trend-spotting and understanding the *longue durée*. It may be that a concentration on what is currently widespread and important in education can distract from the long-term, significant movements. Speaking of the crusades, Fletcher writes: 'Attitudes laid down like rocks long ago continue to shape their moral environment for many centuries thereafter. There is a geology of human relationships which it is unwise to neglect' (Fletcher, 2004: 159).

The *longue durée* forces operant on education are often military-political as in the European conquest of America or the centuries-long decline of Byzantium. They may also be cultural-political as in the Reformation in northern Europe or the deliberate attack on tradition by communist forces in the PRC or the former Soviet Union. These forces are sometimes straight ideological as in nationalistic elements which since 1789, say, have come to inform much of normative social and educational knowledge across a wide range of states. These forces can also be economic-technical as witnessed by the global spread of universities and in particular their Science, Technology and Engineering faculties. It would not be helpful to try to generate a strict typology here as these forces often come together: Islam as well as Arabic expanded geographically in the second half of the first millennia CE.

Nor are these forces uncontested: Catholicism spread with Spanish across Central and South America but at the local level it was a version of that religion which would have found little approval at the Council of Trent. Similarly, resistance to western science and technology remains exceedingly widespread. On the one hand this may be represented by lunatic fringe, though nevertheless influential, anti-evolution Christian fundamentalists in the USA and UK. On the other hand there is a more rational critique of the effects of western science and technology on the environment and on humanity itself. Emerging, inter-related crises of climate change and hydrocarbon exhaustion are the products of humanity's use of science and technology. It is highly unlikely that any solution to these difficulties – if such there is to be – will be derived exclusively from the scientific paradigm. There is not going to be some wonder science that can reverse global warming and generate infinite amounts of energy from sea water. No matter how powerful the social, economic, military or intellectual force, it will not be unopposed and, in the *longue durée*, it will reach its limits. Peak oil has already probably passed (Klare, 2005; Roberts, 2005).

The task of this chapter, then, is twofold: firstly to identify the current trends, attention to which might serve to distract from understanding the *longue durée* forces or indeed to ignore or misunderstand them completely; secondly to try to identify the *longue durée* forces which will lead to significant lasting change to what is taught in schools and universities. The immediate focus of the chapter is on educational institutions and religion but the exemplifications occasionally range beyond this. If this were a straight trend-spotting chapter it would obviously devote more attention to the impact of information and communications technology (ICT) on educational institutions and society (Brown & Davis, 2004). From the perspective developed here ICT is a further advanced manifestation of that science and technology developed and advocated inside the Enlightenment paradigm.

The Distraction of Current Trends

The attack on the World Trade Centre in New York was a manifestation of terrible murderousness. The appalling loss of life has rightly been universally condemned. In the toll of recent human murderousness it does not stand alone. It may be set, for example, alongside events in Szerbrinita or Dafur. September 11 was not a unique event though the very fact that both reader and author have internalised this date might imply that it was. What was unique was that it was an attack by an outside force on the territory of the USA. This has not happened since 1814. And in the period since 1814 the USA has become the uncontestedly most powerful state on earth. With this power the USA is uniquely able to inscribe its version of events across global consciousness. The result of this has been that the destruction of the World Trade Centre and the attack on the Pentagon are increasingly seen as a landmark event in both recent history and social consciousness. This may be exemplified by the use of the current term, 'post-9/11.'

In political terms the results have been major changes in US policy both foreign and domestic. In foreign policy the 'war on terror' has been used to justify military interventions as diverse as the Anglo-American occupation of the Iraqi oilfields and Putin's remorseless persecution of the Chechens. In domestic terms the event has become a justification for the erosion of civil liberties both in the USA and beyond, to the extent of the illegal imprisonments at Guantanamo Bay and the widespread sanctioning of the torture and mistreatment of enemy combatants and civilians.

It is perhaps early days to attempt to discern the influence on educational policy, or, more precisely, educational policy analysis. But one trend has already been widely identified by commentators and that is fundamentalism and its perceived rise (Burleigh, 2007; Duijzings et al., 2002; Leirvik, 2004; Micklethwait & Wooldridge, 2005; Soon-Yong, 2004; Victor, 2005; Zambeta, 2000). For the warriors on terror, fundamentalism is something that is automatically equated with Islam so that, in the extreme (but widespread), xenophobic version, all Muslims are fundamentalists and all fundamentalists are Muslims. More balanced commentators have noted fundamentalism on either side of the conflict, noting the extreme Protestant background of many of the American proponents of the war on terror, their links with the militia movement as well as their fervent support for the Israeli occupation of the West Bank and (previously) Gaza. Others (Sim, 2005) have claimed to discern a more general shift to fundamentalism including such diverse phenomenon as: Al-Qaeda, the Muslim Brotherhood, Hare Krishna, globalisation, Le Pen, Pim Fortuyn and the American militias. This holistic fundamentalism will be considered in due course. At this stage it is worth concentrating on the apparent clash of fundamentalisms eloquently evoked by President Bush when he referred to the war on terror as a crusade. The fundamentalisms here then are religious and historical: they have been produced and reproduced by educational transactions and institutions since at least the bloodthirsty sack of Jerusalem by the Christians in 1099. On the one hand are the anti-science, anti-women curricular aspirations of the fundamentalist neocons in many of the states of the USA, on the other the (also anti-science, anti-women) curricula of the Taliban madrassas. Education is seen as being taken over by the fundamentalists. This trend may be seen to be both pervasive and widespread. Pervasive in the penetration of the Greek school curriculum by

orthodox religion (Xochellis & Toloudi, 2001; Karakasidou, 1997; Mazower, 2001) or the hatred curriculum of the madrassas of north-west Pakistan. Widespread in that, in various states, Hinduism, Islam and fundamentalist Christianity would all appear to be on the rampage in both school and society.

Before going on to assess this trend it is appropriate to consider the role of the comparative or international commentator on education. This is not a matter of solipsistic concern with 'method', the fatal attraction of which almost brought about the institutional destruction of comparative education in the recent past. It is that, in dealing with more than one value system and in particular in considering value systems different from that in which the commentator was brought up and educated, it is necessary to consider the appropriate intercultural stance. To analyse one fundamentalism from the perspective of another is to engage in fundamentalism per se rather than social commentary. Cultural relativism has long seemed to offer some protection from the dangers of various orientalisms. The theme of fundamentalism is appropriate to a postmodern, relativistic approach in which all cultural and political forces are treated with an equal calm remoteness. This approach would seem to avoid the possibility of bias, of being committed from the outset to a particular grand narrative. Whilst this is appropriate to a point, and has been a stance much preferred by commentators in, say, intercultural education, it is not entirely sensible for educational discourse to imply equality of esteem between *Genesis* and *The Origin of Species*. There comes a point at which the postmodernist is in danger of implying parity of esteem between peace and war, between tolerance and intolerance, between truth and error. In the selection of the knowledge to be reproduced in schools and universities all decisions are informed by values. To claim that a selection is value-free is likely to be privileging a particular sort of orientation, almost certainly one derived from the Enlightenment. The claim to value neutrality is rarely other than disingenuous. It may be best then for commentators to acknowledge their background and let the reader make allowance for commensurate bias: I am not religious but have been educated in the European humanistic, scientific and artistic tradition.

The current climate of perceived fundamentalism might be misleading in terms of understanding the *longe durée* forces currently operant on society and education. Given the events of the first decade of the twenty-first century this climate is understandable. As this chapter was being written, four young men, educated in English schools and, in some cases, universities, bombed the underground railway and a bus in London. Reborn nationalism in Russia and Serbia and Bush's war on terror, can all too easily link in to fundamentalist forces for their power and justification. Even the sacred economic orthodoxies of the Breton Wood institutions can link with and reinforce these fundamentalisms in terms of the manifest destiny of new imperialisms. But such a sweeping analysis might be to identify schools and universities across the world too closely with the madrassas of north-west Pakistan. Other, less sensational but more enduring forces are at work on educational institutions.

Two examples might illustrate the ways in which the picture is appreciably more complex and conflicted than the triumph of fundamentalism. In both cases it is appropriate to note that radical changes do occur in schools and society but that such changes are far from a frequent occurrence. Fundamentalist Protestantism, firstly, has had a pervasive

influence on politics and society in the USA for at least the last 30 years. It has influenced the formation of institutions and the contents of curricula at all levels of education. But this influence in fact has been superficial. The common school of the USA is not yet in danger from these forces, nor is the teaching of Darwinian Science at Ivy League Universities. Traditionalist strands in the curriculum of the USA are more characterised by nationalism, and indeed xenophobia, than they are by religion. The nation-building function of the American education system remains fundamental and indeed is being renewed in the face of rapid demographic change, not least the expanding Hispanic presence in southern California. The precepts of the Constitution were designed to meet such challenges: it is unlikely that they will be overthrown by religious fissiparousness, no matter how politically influential this may be in the short term. Secondly, in the PRC the curricula of schools and universities have been radically politicised since 1949. Indeed the Cultural Revolution of the late 1960s and early 1970s provides one of the most extreme examples of the politicalisation of education in the whole of human history. Yet beneath the surface other less radical trends characterise the development of Chinese education: the spread of the Han Chinese language, the development of technical vocational subjects, the blossoming of excellence in music and sport, the emergence of world class universities. Whilst the West is shocked at the severity of the repression of Fulan Gong, Llamist and Confucian ceremonies are openly celebrated in urban as well as rural shrines and temples. The point is that looking backwards through the revolutions of 1949 and 1911 there are continuities in Chinese history and politics: the centralisation of policy, the diffusion of the Han language, a regard for the cultural and technical excellence of the products of the Middle Kingdom, an awareness of at least equality of esteem with interloping western values (Fairbank & Goldman, 1998; Fewsmith, 2001; Massonnet, 2000; Nathan & Gilley, 2003; Roberts, 2003; Starr, 2001; Studwell, 2003; Terrill, 2003). The Mandate of Heaven has been renewed in surprising ways across the millennia, by Mongols and Manchus for instance. The dislocations of the twentieth century may similarly conceal the persistence of China.

As well as fundamentalisms, then, other forces are operant on schools and society. Obviously, as is clear from the two preceding examples, these will differ between states. However, predominant among these *longe durée* forces are the ongoing impact of the Enlightenment Programme together with its negative alter ego of imperialism and nationalism. The tendency in education has been to see the Enlightenment retrospectively in terms of its major impact on institutions and knowledge itself. One difficulty with this is that it tends to refer to a rather nebulous Enlightenment Project without actually analysing particular thinkers or policies (Lyotard, 1984; Jameson, 1991). In fact the Enlightenment is the product of many thinkers operating in a wide range of intellectual areas and it is impossible to tie it to a few prominent figures. When considering the work of the Encyclopaedists, Kant, Hume or Tom Paine, they seem far from the work of a unitary project. The Industrial Revolution and the French Revolution both clearly derive from the Enlightenment but despite their origins they followed different and at times apparently contradictory trajectories (Hobsbawm, 1975).

In 2003 the British Museum reopened the King's Library as its Enlightenment Gallery. In doing so it both boldly asserted its own importance – 'The foundation of the British Museum was one of the most potent acts of the Enlightenment' (Sloan & Burnett, 2003,

p.13) – and attempted to rediscover the Enlightenment within the terms of its own period. One of the impacts of this gallery is the sheer amount of material, natural and artificial, that it contains. Not only is the range of material vast – sculptures, ceramics, butterflies, books, geological specimens and so on – but so is the actual quantity. The large gallery is chocked full from floor to high ceiling. One principle of the Enlightenment was simply collection, this preceded and perhaps even superseded organisation. Enlightenment intellectuals were not overawed by the vastness of either nature or human achievement. They saw both as their fields of endeavour, even of pillage. It was on this framework that the Enlightenment became ‘a period when the principles of classification, taxonomy itself, came into their own’ (p. 13). Rationality, progress, truth and liberty are the abstract nouns of the rhetoric of the Enlightenment. The political and philosophical ideals of the Enlightenment impacted on the American and French revolutions and thus on succeeding centuries. But in intellectual and educational terms, it is the spirit of collection and enquiry that should be stressed; the spirit that believed that the natural and civilisational universes could be gathered, rationally organised and understood. It is easy to see that postmodern scepticism would perceive this as the attempt to contain the whole of nature and the whole of human achievement within a grand narrative of taxonomy, indeed within a museum. Nevertheless, it is that spirit of undaunted enquiry, that relentless search for increased understanding of all areas of rational thought that has characterised the impact of the Enlightenment on the knowledge of schools and universities. Despite the differences and limitations of its individual thinkers, it is within this strand of the Enlightenment that fundamentalism confronts a clear antithesis (Dawkins, 2007).

This strand of enquiry was in many cases secular and indeed anti-clerical from the outset, Gibbon as well as Voltaire. It was to prove devastating in its consequences for organised religion and belief. In geology as well as natural history, indeed in studies into the origins and nature of the biblical texts themselves, the Enlightenment spirit of enquiry undermined the teachings of the bible. As increasing areas of knowledge were opened to the flood of rational enquiry the terrain of inerrancy disappeared. Religion became no longer a matter of knowledge but of faith, furthermore of a faith which had to stand in the face of an ever increasing and varied amount of well established knowledge. The publication of *On the Origin of Species* in 1859 represented both a culmination and a symbol of this process. Darwin had delayed publication for fear of the effect his work would have on organised Christianity and the controversy he provoked was profound and is still surprisingly ongoing.

Many Enlightenment thinkers and scientists had supposed that progress would sweep organised religion, in particular Christianity, into the dustbin of history (Hume, 1993; Paine, 1998). Of course, to a large extent this has happened. But organised religion remains a thriving institution in many states and a key component of identity formation for huge groups of people. Two main reasons may be given for this strange survival, both of them educational. Firstly, in many states of Europe religious institutions had infiltrated schools and universities prior to and during the Enlightenment period. The control of many schools and universities in the UK, the Netherlands and Greece, for example, meant that religious dogma could be reproduced alongside Enlightenment knowledge. The very framing of Enlightenment rationality was performed by institutions and personnel committed to the traditional, the irrational. Secondly, postmodernity

itself has offered prolonged protection for religions. Enlightenment knowledge was the grand narrative most suspected by postmodernists. If all truth was relative then religious diversity would be one of the hundred flowers permitted, even encouraged, to bloom. Thus, in the UK, state Catholic, Protestant and Jewish schools have in the last decade been supplemented by those representing Islam, Greek Orthodoxy, Hinduism and even anti-Darwinism. Postmodernity has encouraged traditionalist beliefs and practices and, in the revived guise of fundamentalism, these have proved hostile and destructive to Enlightenment knowledge itself.

In the light of the terrorist bombings in Madrid and London it is likely that there will be a reassessment of the European approach to multicultural societies and intercultural education. Of course a strong element of this reappraisal will be the traditionalistic nationalism and xenophobia which have always opposed cosmopolitanism. But another element will raise the issue of the anachronism of any kind of religious involvement in schooling in these highly globalised states. Following the attacks in London, *The Guardian* published a poll which reported two thirds of people in the UK to be opposed to any form of state aid to religious schools, including those run by Protestant and Catholic churches (Taylor, 2005). It is important at this point, then, to keep a sense of perspective and not to be over impressed by the continuation and revival of traditionalistic beliefs and practices. In terms of the long-term development of the Enlightenment spirit of enquiry these are minor phenomena and their impact on educational institutions is strictly limited. Whilst it is unequivocally regrettable and bizarre that a few secondary schools in England should indulge in anti-Darwinism, the development of science is not seriously impeded. Such indulgence is having no serious impact on the research programmes of laboratories in the Universities of London, Oxford and Cambridge. Whilst the sponsorship of Islamic schools, or for that matter Catholic, Protestant or Orthodox schools, by modern states is anachronous and anti-educational, the grip of religious institutions over the minds of young people has been steadily loosening over increasing areas of the globe since the Enlightenment.

Nationalism and imperialism have long been perceived as the down side of the Enlightenment. Whilst this may be argued in the instance of specific thinkers – imperialism hardly characterises Tom Paine, for instance, or even the slave owning Jefferson – nationalism was one of the forces which expanded across Europe and beyond with the armies of the Revolution and Napoleon. The increased trade generated by the Industrial Revolution, and conducted in the first instance by national trading companies, allowed ultimately the global penetration of European activities and ideas. The trading companies' 'intervention in local affairs – social, political and economic – grew stronger as increasing national support came not only in diplomatic but also often naval and military form. Thus while the Museum's natural history and ethnographic collections and British understanding of their history and cultures grew as a result of the activities [of the trading companies] ..., so the growing level of intervention by British and other foreign governments often ensured a concordant alteration of those same cultures. As Kant declared in 1784, this was the age of Enlightenment, but not an enlightened age' (pp. 24–25). The conquest of much of Africa, Asia and Australasia were to follow. Imperialism was the major mode of dissemination of Enlightenment knowledge. The cultural confrontations which resulted and which are ongoing in terms of globalisation form the basis of conflict

over much of the school and university curriculum in most states today (Burbules & Torres, 2000; Coulby & Zambeta 2005; Stromquist & Monkman, 2000). The opposition of the Enlightenment project to fundamentalism indeed to religions in general is neither a matter of a clash of civilisations nor some eschatology of epistemological right and wrong. The Enlightenment project has been far from an unmitigated blessing in terms of school and university curricula. The task of separating rationality from nationalism and racism in this respect has only just started. The postmodern critique of Enlightenment knowledge is not misconceived though it has proved unaware of the perils of other discursive strategies of knowledge.

Nationalism and imperialism may themselves now be seen as part of the process of globalisation. And globalisation represents the principle force currently operant in most states on both education and religion. The process of globalisation has many aspects and it has impacted on schools and universities in a variety of ways, not least through the development of the knowledge economy. However, given the focus of this chapter, it is the cultural dimension of the globalisation process which is considered here. Three cultural dimensions may be considered: language, nationalist history and culture and mass culture. The first two are important components of the school and university curriculum. The third, mass culture, stands potentially in opposition to them.

Firstly, in terms of language, the economic, political, technological and cultural activities which characterise the globalisation process are all conducted in English. Air traffic control, scientific and learned journals, the Internet, Hollywood movies, pop music, international conferences and diplomacy – all are conducted predominantly and increasingly in English. English is the first foreign language taught in almost every school system in the world. Increasing numbers of university courses are being taught in English even in non-Anglophone states. As international mobility among university students increases it is overwhelmingly the English speaking countries which are the destinations of choice. Fox, CNN and BBC have virtually global reach thus extending not only the English language but an Anglo-Saxon view of current events. However, English is not the only language which appears to be on the march. Although the spread of Russian has been halted and reversed, Han Chinese is a language which is increasing both its numbers and its geographical presence in Xinjiang, for instance, and Tibet. Nor is the spread of English language in any way a process which is unresisted. Each time an educational system or individual school elects to have a different or even a second foreign language the hegemony of English is resisted. This resistance has political significance in France as well as in the Arab world.

Secondly, nationalist history and culture have long been identified as fundamental features of educational systems especially at school level (Coulby, 2000). With the intensification of globalisation this role takes on a beleaguered significance. In the face of the tsunami of mass culture, the globalisation of the economy and the decreasing importance of individual states as international groupings such as the European Union increase their powers, countries such as France or Greece use their schools to stress their importance to the world in historical and cultural terms. Power may have shifted from Athens and Paris to Brussels and Washington but, in the school-inscribed identity of the individual, Waterloo can be assuaged, Byzantium retrieved. It is the contention of this chapter that traditionalism is gradually being eroded from society and educational institutions, but nationalism is

proving the most resistant of its elements. (Postmodern forms of cultural and identity hybridity are one of the most adaptive and even justifiable forms of this resistance, rather than the emergence of a new episteme.) This is not to say that nationalism cannot be intrinsically connected to religion as is certainly the case in Pakistan as well as in Greece. However, the trend has been, since at least the Enlightenment, for nationalism to supersede religion as the core element in identity and state formation. Current events in the USA or Saudi Arabia, notwithstanding, this trend is clear in, to use historically significant examples, Belgium, Spain, Mexico and Russia. When nationalism takes on a religious dimension (a common feature of fundamentalism) it certainly manifests one of the currently most successful resistances to modernity in both societies and schools and madrassas. It is likely that the school curriculum will remain one of the last bulwarks of nationalism and xenophobia whether or not religiously inscribed. However, it is the university which is increasingly the internationally significant institution of the Enlightenment and here the curriculum is gradually escaping its nationalistic construction.

Mass culture is the third and final cultural dimension of the globalisation process to be considered here. It is connected to the first, language dimension, considered above in that it is overwhelmingly transmitted in English: films, television programmes, popular music, newspapers and magazines, computer games and the internet. Where it is not transmitted in English, these media have often been created in English and then translated or distributed with subtitles (Crane et al., 2002). Indeed such is the potency of English in this area of subculture that popular music or advertising media are frequently composed and presented in English even where that is not the language of the society. This is not to deny the validity or global reach of mass culture in other languages: films from Cairo and Mumbai, television programmes from Brazil, international news broadcasting in Arabic, French and German. But the aspiration of the most successful proponents of mass culture is almost always to operate and market in English. The growing economic strength of China is likely to increase further the spread of the Chinese language. But whilst the number of its speakers may for a while outnumber the speakers of English, it is unlikely to be able to compete with the latter's global reach or penetration of international mass culture. Both religious and educational institutions have sought to incorporate and manipulate mass culture both as a form of resistance and as a way of seeking a way of appealing to young people. Nevertheless, the appeal of mass culture and its separation from and disdain for religious institutions and values is surely one of the forces serving to undermine fundamentalism: hence the widespread opposition to mass culture by the proponents of fundamentalism.

To recap: other forces than fundamentalism are currently operant on societies and educational institutions. Predominant among these is the ongoing impact, far from exclusively positive, of the Enlightenment Project. Furthermore these forces are themselves currently subject to the process of globalisation. In cultural terms the spread of and resistances to American cultural products is a global process. ICT has notched another ratchet on the progress of the Enlightenment Project in terms of communication and dissemination as well as electronic engineering. The Enlightenment agenda of science and rationality has become a global movement at least at the level of higher education. From the point of the *longue durée* then it may be that the impact of fundamentalisms will remain epiphenomenal.

Globalisation has itself thrown up trends which superficially would appear to be transforming education such as the spread of pragmatic capitalist business practice and theory and its educational embodiment in Business Studies and the currently ubiquitous MBA. Compared to the ground-shifting transformations caused by the developments in ICT these will be seen as but brief fashions. In the decline of religion there will be periods of revitalisation, fusion or extremism. In order to avoid the risk of secular fundamentalism the task of postmodernity will be to tolerate and learn from all differences whilst retaining and developing, no matter how hybrid, the perspective of rationality. The spread of the English language and its associated cultural products and values; the apparently unstoppable momentum of Enlightenment science and technology: these are the forces, contested and conflicted in a range of settings, which, in international terms, are currently transforming schools and universities.

THE DOUBLE GESTURES OF COSMOPOLITANISM AND COMPARATIVE STUDIES OF EDUCATION*

Thomas S. Popkewitz

It might seem a contemporary cliché when I say that my thinking about comparative education is in a context of globalization. Intuitively, what else can the study of comparative education be except in a broader field that takes into account cross-national and “global” changes? As I say this, I admit a hesitation as “globalization” has the status of the planetspeak, to draw on the work of António Nóvoa (2002). It is a word that appears “everywhere” to explain everything, and without any author. My hesitation, however, is tempered historically, in part, through the insights of world systems studies and neo-institutional theory that relate the formations of the modern school and nation-forming from the nineteenth century to the present (Meyer et al., 1992, 1997).

My interest, however, enters the comparative study of schooling from a different intellectual terrain. This chapter focuses on the systems of reason through which the objects of schooling – the child, family, and teacher – are produced and administered. That is, schools are historical sites to change society by changing people. That is what pedagogy does. Modern pedagogy is the major social/cultural site where children are taught how to reason and problem solve and to become “reasonable people.” The principles of teaching and learning, I will argue, are concerned with the production of “reasonable people” through generating cultural theses about modes of living. The cultural theses are not merely variation of a single theme such as modernization or globalization. If one looks at the Chinese school reforms of May 4 Movement in 1919, US Progressive Educations, or current discourses about the Learning Society and the Lifelong Learner, they entail different cultural and institutional assemblies and connections about who the child and teacher are and should be. Understanding schools comparatively, then, is in considering historically the changing principles generated as the cultural theses of who the child is and should be.

My approach to the comparative qualities of the system of reason of schooling is through the notion of cosmopolitanism (Popkewitz, 2008). Cosmopolitanism, I argue, is at the heart of schooling. In its northern European Enlightenment traditions, cosmopolitanism embodied the radical thesis about human agency, participation, and science as an emancipatory project of humanity. That enlightened individual places faith in the application of reason and rationality in directing change, and for the self-improvement and progress of society that respect diversity and hospitality and compassion for

* The thesis of cosmopolitanism and reform is drawn primarily from Popkewitz, 2008.

“Others.” Schooling, or at least modern schooling, is concerned with the making of the child as the future citizen of the nation who embodies cosmopolitan characteristics. Further and oddly enough, the reason of the cosmopolitan that was to be inclusive embodied comparative inscriptions to order the phenomena and people. The “reason” of European modernity recognized and differentiated “others.” When brought into schooling, the very universalizing principles about humanity and emancipation of the pedagogical practices carried its opposites, the child who did not “fit” in and thus was excluded from the inscribed qualities and characteristics of the cosmopolitanism.

The cosmopolitanism in schooling, however, is not merely the dissemination of Enlightenment notions in a world system. Rather, there are different assemblies, connections, and disconnections that produce cultural theses of the cosmopolitanism of the child and collective belonging. The reason and “reasonable person” in pedagogy are linked with principles of collective belonging and home. This might sound ironic, as the European cosmopolitanism was to shed the provincialism of the nation. Yet it did not and its particularism is embedded up to the present in schooling. The “enlightened” individuality was not the same “person” in the making of Brazil, Belgium, Japan, or Britain.

The first section considers schooling as embedded in processes of globalization in the long nineteenth century to the present.¹ The analysis draws from the US and Europe educational “reform” sciences and policies concerned with restructuring teaching and teacher education. I argue that the modern schooling was to remake society through remaking the child who was to become the future citizen.² Pedagogy embodied cultural theses about the mode of life of that cosmopolitanism. But embodied in pedagogy were comparative distinctions to differentiate and divide “the civilized” cosmopolitan from “the uncivilized.” The next section explores the traveling of Dewey’s pragmatism as a historical exemplar of cultural theses about cosmopolitanism and its “Others” in reforming society at the turn of the twentieth century. The final section looks at the comparative instantiations of cultural theses in contemporary school reforms. It examined what I call the unfinished cosmopolitan who is the lifelong learner that lives through the continuous making of choices and innovation and its Others – the disadvantaged, the at-risk, immigrant, and the “child left behind” who are recognized for inclusion yet cast out as different and potentially dangerous to the stability and consensus. The final section draws the analysis into considering the theoretical implications of cosmopolitanism as cultural theses for comparative studies of schooling.

My use of cosmopolitan is diagnostic and not normative. It is to consider the distinctions and differentiations that partition sensibilities in ordering children’s cognition, problem-solving, and collaboration in “communities of learning,” to use commonsense words of contemporary reforms. The “ism” of cosmopolitanism is to give attention to the different assemblies and connections through which the principles of reason and reasonable people are produced rather than to treat the word as a distinctive doctrine.

Modern Schooling in a Historical Context of Global Processes

Four brief points raised in the introduction are discussed. First, modern schooling is embedded in processes of globalization from at least the long nineteenth century to the present. Second, the notion of cosmopolitanism is a strategy to consider the changes in the cultural

theses about modes of living in schooling. Third, the sciences of school pedagogy inscribe principles of reason that ordered the cosmopolitanism of the child. Fourth, the universal, transcendental qualities of the cosmopolitan child embody a comparative method that inscribes the cultural thesis of the cosmopolitan child and processes of abjection that differentiates, casts out and excludes particular “other” children in processes of inclusion.

1. Modern schooling is embedded in processes of globalization that relate to changes associated with the long nineteenth century. This does not mean that there are no continuities and overlapping with prior schooling, as the historical studies of David Hamilton (1989) continually illustrate. Rather, particular configurations of contemporary schooling become apparent through changes in pedagogy and its theories of the child.

The purpose of modern schooling is to *remake society through remaking the child*. The founding figures of the American and French Republics recognized this. The citizen was not born but made. Democratic participation was “something that had to be solicited, encouraged, guided, and directed” (Cruikshank, 1999: 97). The maintenance of the nation was dependent on making the citizen who was self-governing and participating in social affairs.

Education was central in making of the individuality on whose participation modern government was dependent. One might say that the problem of social (re)construction of society through schooling was placed at the foot of the child. Mass schooling was seen as essential to the producing of the individual who embodied the transcendental principles of nation. Brazilian, Mexican, Columbian, and Chinese school reforms into the early twentieth century, for example, embodied cultural theses about the child’s reflection and participation that linked salvation notions of the individual with the nation (Buenfil Burgos, 2005; Warde, 2005; Qi, 2005; Sáenze-Obegón, 2005). The Swedish Torsten Rudenschöld in the 1800s spoke of a cosmopolitanism when thinking of the school as producing “the free will of individuals” in society (cited in Hultqvist, 2006). The introduction of the vernacular language in China after the May 4 Movement of 1919 can be read as well as bringing a different relation between people and collective belonging, albeit different from that of European and North American schooling (Qi, 2005).

2. Central to the pedagogy of the school was cultural theses about the cosmopolitanism of the child. Both in the West and outside of it, notions of cosmopolitanism emerged to join secularization processes of individual agency and progress with salvation themes of redemption that was tied to the nation that had some irony. The northern European and North American Enlightenments spoke of cosmopolitanism as a universal mode of living in which reason and rationality provided for a more progressive world of freedom and liberty. That cosmopolitan world was quickly inserted in the particular narratives and images of nations. The different progressive pedagogical ideas embodied in John Dewey, G. Stanley Hall, Edward L. Thorndike, and George Counts in the twentieth century, for example, inscribed cosmopolitan principles in the planning of schooling and the child. These principles embodied cultural narratives about “American exceptionalism,” the nation as an epic account of the progressive development of the highest ideals of cosmopolitan human values and progress.

3. Cosmopolitanism joined science with reason in effecting change in one's own life and community. As the physical sciences could master the natural world, science was viewed as a way to order and artificially intervene in the natural order to effect change and human progress.

The notion of human science, however, had different configurations in providing for change. Science provided knowledge, for example, about the planning that enables conditions for the pursuit of happiness and liberty. Urban planning: the formation of the modern welfare state, were instances of the relation of science to finding the right mixture of knowledge and strategies for social development. Reform became a constant activity. And that reform of society also entailed principles for governing the cosmopolitan society through planning modes of living. The sciences of pedagogy, for example, made the interior of the child a site of intervention. Dewey's problem-solving and Hall's child development and growth gave an order to life through designing the processes and procedures of "thought" that gave consensus and stability to the rules and standards applied for action and the future.

Psychology is central to pedagogy. If I focus on Europe and North America, psychology opened up the interior of the child as the site of calculation and intervention in the pedagogical. Speculative and analytical psychologies were replaced with experimental psychologies in diverse sites that moved across Russia, Germany, and the US. The beginning of modern schooling, pedagogy, and its sciences of education, Ó (2003) argues, was designed to act on the spirit and the body of children and the young. Examining French and Portuguese pedagogy at the turn of the twentieth century, Ó explores the method of the pedagogical sciences as observing and making visible the inner physical and moral life in order to map the spirituality of the educated subject ("the human soul"). The French pedagogue Gabriel Compayré in 1885 asserted that pedagogy is an applied psychology and the sources of all the sciences "that are related to the moral faculties of man; pedagogy contains all the parts of the soul and must use always psychology" (cited in do Ó, 2003: 106). The purpose was, however, not to find God but to provide knowledge that helps to free man through the path of reason.

The narratives of cosmopolitan reason and science embodied salvation and redemptive themes that traveled along with practices of rationalization. In an almost counterintuitive sense, Western mass schooling cannot be adequately understood without understanding the Reformation and Counter Reformation. Themes of individual salvation were secularized as earthy concerns of progress and the organization of daily life (Weber, 1904–1905/1958) that become embedded in constructions of modern pedagogy (McKnight, 2003; McMahan, 2001). The secularization and modernization processes of the Kemalist Revolution in Turkey during the twentieth century, as well, entailed modernization processes that assembled European enlightenment projects with those contained within the Ottoman Empire and its Islamic traditions (Kazamias, 2006). A similar argument can also be expressed with the Japanese modernization processes associated with Meiji reforms of the middle nineteenth century to the post-World War II constructions of the state and schools (Shibata, 2005).

4. *While the impulse of cosmopolitanism is inclusionary, its system of reason entails double gestures that excluded.* Cosmopolitanism entails comparative methods that differentiate and divide the qualities and characteristics of those who are enlightened and civilized from those who threaten the consensus and stability – the “uncivilized” person who was called “backward,” “savage,” and the “barbarian” in the nineteenth century and today’s at-risk and delinquent child.

The comparative method inscribed in cosmopolitan reason was a particular historical practice that had different trajectories. The analytical qualities of modern science and medicine are made possible through the comparison of “things” and parts as it relates to some unity of the whole. Comparative installations also entered into social and cultural practices through classifications and differentiations formed a continuum of value and hierarchy that placed “man” in a continuum of people and civilizations that was “seen” as moving from advanced to less advanced and uncivilized. Modern historicism as narratives that linked past/present/future appeared, for example, in the nineteenth century. It provided ways to talk about nations as tracing their histories through progressive developments of “civilizations” that started in Ancient Greece or Rome and arrived at the present; and at the same time, ways of justifying colonialization.

The rationality and reason of cosmopolitanism visualized the civilized and their hospitality to others through the recognition that demarcated difference. The comparative quality functions to differentiate and divide those capable of cosmopolitan “reason” and thus given as the civilized people from those in other cultural spaces – the individual whose qualities of life are given classifications as “not as advanced.” The differentiations and divisions are embedded in modern philosophy, the human sciences, and schooling (Rancière, 1983/2004). Theories of the human sciences made the arbitrariness of differences into necessity and inevitability. The recognition of difference stabilizes groups as outside normalcy and “incapable of ever acquiring a taste for the philosophers’ goods—and even of understanding the language in which their enjoyment is expounded” (Rancière, 1983: 204).

Cosmopolitanism, then, provides a historical strategy to consider reason as simultaneously systems of inclusion and exclusion in schooling historically and across different social-political spaces. The universal and inclusive practices of school reforms that speak about “all children” as a gesture to unify the whole of humanity are, I will argue, processes of abjection in which the divisions are produced that cast some qualities and people as outside of the spaces of inclusion.³ Today’s reforms that speak about an inclusive society produce unlivable spaces that are occupied by the disadvantaged, the urban child and family, the poor, and the immigrant, and, as I will argue from the US context, the child “left behind.”⁴

Cosmopolitan “Reason(s)” and Globalization at the Turn of the Twentieth Century: Dewey as Conceptual Personae

In this section I explore cosmopolitanism historically as an intellectual “tool” in which to consider the cultural theses generated through pedagogy, and its systems of abjection. I focus on the traveling of John Dewey’s pragmatism as is a cultural thesis about enacting

the cosmopolitan life that is not merely that of Dewey.⁵ Dewey functions as a *conceptual personae* (Deleuze & Guattari, 1991/1994), enunciating particular solutions and plans for action within a grid of social and cultural practices that give the “ideas” intelligibility. As Dewey was the international salesman for American pragmatism at a time when mass schooling was institutionalized in diverse cultural and political fields, the encounters with and rejections of pragmatism provide an initial comparative strategy to consider the principles interning and enclosing who the child is and should be.

Pragmatism and the Planning of the Cosmopolitan Self

Dewey’s pragmatism embodied a cosmopolitan that presupposed the individual as a purposeful agent of change in a world filled with contingency. That agency brought notions of science into a process to order life as a continual and changing set of problem solving. The science that Dewey spoke about was not about what physicist or biologists did. It was a cultural thesis that brought Enlightenment notions of the transcendental power of reason and progress as a habit of reflection and action. Dewey said that since “the future of our civilization depends upon the widening spread and deepening hold of the scientific habit of mind, the problem of problems in our education is therefore to discover how to mature and make effective this scientific habit” (cited in Diggins, 1994: 227).

The “habit of mind” embodied a particular reform Protestantism of northern Europe and North America at the beginning of the twentieth century. Dewey saw no difference between a universalized notion of Christian values about the good works of the individual and the democracy of the nation. It was a twofold response that responded to the moral and physical disorders to the city brought by industrialization and immigration. Dewey and his contemporaries were also concerned with reinscribing Christian values in society thought lost in the unbridled capitalism of the Robber Barons of Carnegie, Mellon, and Rockefeller, among others. These values were about the individual’s social obligations in performing “good works” linked to the general welfare of society.

Dewey’s pragmatism entered into an international field in reforms related to changes in politics, society, and individuality (Popkewitz, 2005). The travels of Dewey’s notions of agency, “intelligent action,” problem-solving and community in the writings of Dewey functioned in traveling libraries as amalgamations of different sets of ideas in which cultural theses were produced about modes of living. The ideas and concepts of Dewey, for example, are assembled with the Swiss pedagogue Claparède and the Belgian Decroly in South America as national reformers sought to bring into being “the New Education,” a name given to a variety of efforts to reform the school through scientific principles.

While Claparède, Decroly, and Dewey traveled together in many places, there were different amalgamations of the texts in constructing cultural theses of who the child is and should be. Decroly translated Dewey in a Belgian missionary, evangelistic, and propagandistic pedagogical discourse (DeCoster et al., 2005). Pedagogy was to keep Christian doctrine as a safeguard of the order of progress through ordering children’s lives. Dewey was assembled in Columbia through Decroly and “local” authors, in contrast, as a reactionary and conservative pedagogy (Sáenze-Obegón, 2005). Dewey and Decroly were placed in the company of the German Kerschensteiner and the Swiss Claparède as the philosopher of a social redemption that Yugoslavian pedagogic work

would produce to center on the child's activity. Dewey joined Georg Kerschensteiner and Adolfo Lima in the Portuguese reception, structuring, and relaunching of the so-called New Education.

The different libraries were not variations of a single theme in generating cosmopolitan theses about the child as the future citizen of the nation. The Mexican Revolution discussions of schooling in the early twentieth century joined Dewey's pragmatism in and Catholic religious emblems and traditions with notions drawn from the Enlightenment, rationalism, pragmatism, democracy, socialism, and republicanism (Buenfil Burgos, 2005). The Chinese May Fourth Movement, in contrast, sought to replace the existing hierarchy of the Confucius traditions, with Dewey's philosophical and pedagogical notions as central to introducing vernacular language, literary changes that valued the individual author, and child-centered education to sanctify individual rights through one's location in a group (Qi, 2005). The new pedagogy did not do away with social and political hierarchy; but was placed in a new organization of hierarchy and notion of collective belonging about what it meant to be "Chinese".

The traveling of pragmatism entailed, as well, counter theses to Dewey's cosmopolitan theses. German pedagogues, working within Lutheran traditions and its own vision of its people as the embodiment of culture and humanity, placed Dewey and pragmatism as devoid of spirituality and violating the *geist* of the nation. Brazilian Catholic Counter-Enlightenment Reformers fought against Dewey's pragmatism as an "urban" secularism devoid of the universality and spirituality embodied in Catholicism (Warde, 2005).

My exploration of Dewey as a conceptual personae assembled, connected, and disconnected in traveling libraries is to recognize that the modern school of the long nineteenth century embodied different cultural theses. Further, that individuality is projected in terms of a universal humanity but has particular links of individuality and sociality in creating belonging and "homes." Dewey as a conceptual personae in effect meets other conceptual personae (the Belgium Decroly, the German Kerschensteiner, the Swiss Claparède, the Turkish Yücel, the Brazilian Teixeira, and the Chinese Hu Shih, among others. The changes in the social and cultural practices were global but with these different cosmopolitan images and narratives of the child and society to govern the principles of reason and rationality in ordering life.

Double Gestures of Hope and Fear: Processes of Abjection

The growing optimism about the "eternal promise" of childhood in pragmatism and more generally in the pedagogical reform movements were not only about the child as the future citizen in promised lands. The positive hope of planning was a process of abjection. Salvation narratives in "intelligent action," problem-solving, and community gave recognition to those who had not secured the benefits of the good life, recognized for inclusion yet different.

Those recognized for inclusion and abjected as different were embodied in cross-Atlantic Protestant reform movements about *the Social Question*. The Social Question directed attention to the perceived moral disorder of immigrants, the working class, and racialized groups in cities. Protestant reform politics circulated among the English Fabian Society, German Evangelical Social Congress, the French Musée Social, U.S. progressive politics, and the transatlantic Protestant's Settlement House movements to

change the conditions of the city and to change the new urban populations (Rodgers, 1998). This entailed, for example, the growing consciousness of the limits of market capitalism and urban planning that would confront the debilitating effects of industrialization. Alcoholism, delinquency, prostitution, poverty, and family disintegration were perceived as threats to cosmopolitan aspirations of the different societies. The cosmopolitan urbane gave focus to the urban!

The new sciences of society and education were part of the response to the Social Question. It embodied the hope of a cosmopolitan future and fears of those who did not participate and act as agents of change. The social sciences were to identify and find solutions to the urban contexts. The notions of community and primary group were concepts to overcome the debilitating effects of modernity in the city, for example, in US urban sociology. The theories and studies draw on German social theories about the alienation and abstract qualities of daily life in the city that erased prior pastoral relations of trust and community built through face-to-face relations. The notion of community was urbanized to “fit” the social patterns through which belonging, attachment, and grounding in an ethics of daily life could be articulated in city life. Dewey’s “habits of the mind” and George Herbert Mead’s notion of the *self* arising out of socially symbolic gestures and interactions, for example, embodied this rethinking of community in the context of the social as a method to counteract the debilitating effects of modern urban conditions.

I draw on this history of the social and education sciences as not merely national projects but of a globalization about the planning of society and people through science. The narratives and images were of the cosmopolitanism; that is, an individuality guided by reason and science in effecting human agency and social progress that was given a universalism in its purposes even if those purposes were historically specific. The sciences moved schooling as a civilizing project in the name of the cosmopolitan society, although that society and individuality had differences when examined cross-nationally and culturally.

The Social Question embodied a comparative set of distinctions that I spoke about earlier. The distinctions and divisions were inscribed through the theories and studies that recognized the need to include. The comparative “thought” entailed populational reasoning that ordered groups through probabilistic theories that placed individual characteristics into categories which classified the modes of living of individuals (Hacking, 1990). Populational reasoning, for example, produced particular aggregates of characteristics of people as a unity of the whole that could be targeted interventions. The comparative distinctions also made possible modern theories of race and class. Eugenics, for example, constructed difference and division on physical or psychological distinctions among populations and races.

Cosmopolitanism and Abjection at the Turn of the Twenty-first Century: Cultural Theses of the Lifelong Learner and its Others!

If we move to the turn of the twenty-first century, the cosmopolitanism and processes of abjection entail different assemblies and connections. Today’s cosmopolitanism is talked about through the lifelong learner and the Learning Society. John Dewey is still with us

in this cosmopolitanism but travels in a different global traveling library of psychological constructivism that includes the Russian psychologist Lev Vygotsky (Popkewitz, 1998a). This joining of the two in pedagogy is historically ironic. Dewey wrote to bring Protestant reformist ethics into social policy of the liberal Republic; Vygotsky was Jewish but sought a psychology that articulated the moral commitments of the new Soviet regime. Both are dead now. Their “history” emptied, to borrow from Walter Benjamin (1955/1985). The two “authors” function as universal heroes in the “new” reform pedagogies in contemporary South Africa, Spain, the Scandinavian countries, and the United States, among others.

A globalization of the individual who is a lifelong learner is impressive. Google search (which of course was not possible at the beginning of the twentieth century) brought up 1,090,000 pages under “lifelong learner.” The phrase crosses broad social and political arenas and geographical locations (Fejes & Nicoll, 2007; Popkewitz & Lindblad, 2004; Lawn, 2001; Álvarez-Mendiola, 2006). European, American, and Taiwanese school and teacher education reforms, US Christian religious schools, the rights of patients in medicine, among many others, evoke the term *lifelong learner* as the embodiment of who a person is and should be. The American Academy of Allergy, Asthma & Immunology Lifelong Learner (AAAAI) Bill of Rights, for example, declares the patient “a life-long learner who has chosen to engage in continuing ... education to identify or fill a gap in knowledge, skill or performance (*Academy News*, July 2005, <http://www.aaaai.org>). Since the mid-1980s, the making of European Union identify is in the cosmopolitanism of the citizen who is the lifelong learner. A draft for European teacher education, for example, asserts that teachers’ responsibilities for the future hinge of the development of the child who is the lifelong learner (European Commission, 2006).

My interest in the lifelong learner is not to celebrate it as the contemporary salvation story of the twenty-first century. It is to think about the comparative study of schooling through exploring its cultural thesis of cosmopolitanism and the comparative instantiation of who does not “fit” its notions of reason and the “reasonable” person. Further, while there are distinctions between the cultural thesis of the lifelong learner in Taiwan, Mexico, and northern Europe and North America, my analysis will primarily draw from US and European literatures as exemplars of the problematic of study in which to engage in comparative studies.

What is the Cultural Thesis of the Unfinished Cosmopolitan?

The revelation process of the lifelong learner is living as the problem-solver. Today’s problem-solving of the lifelong learner, for example, evokes Dewey but with a different assembly of ideas, authority relations, and institutions. A Finnish “Life as Learning Research Project” asserts that the lifelong learner is a complex, variable, less structured individual that is flexible and adaptive to multiple demands (www.aka.fi).

The problem-solving is a calculus of intervention and displacement of the ethical obligation for the child. The rules and standards of problem-solving administer the personal development, self-reflection, and the inner self-guided moral growth of the child.

The administration is therapeutic, to fabricate a better-managed, healthier, and happier individual.

The salvation themes of the lifelong learner are realized through collaboration and participation. The governing of action is through communication systems and networks (discourse communities) of the reformed curriculum. Agency is spoken of in psychological notions of problem-solving and the political evocation of voice and empowerment through community participation and collaboration.

Teachers are now partners and collaborators governed through communication systems and networks (discourse communities) in the construction of personal knowledge. The cultural thesis of the teacher is a decision-maker who is “empowered” and given “voice” through partnerships with communities and parents. The teacher assesses the processes of learning and problem-solving to calculate and supervise the making and remaking of “self” and the child’s biographies. The teacher observes the child’s problem-solving processes from a constructivist standpoint in which there are multiple paths to attain answers. The process and choices are what is important to teaching. The teacher is also an action researcher who reworks herself and the child through a continual construction of life histories or portfolios.

Belonging is no longer directed toward a single public sphere but in diverse communities and individuality that constitute the common good. Emotional bonds and self-responsibility are circumscribed through networks of other individuals—the family and the community. One works actively in “communities of learning” or “discourse communities” as life is a continuous course of personal responsibility and self-management of one’s risks and destiny.

The narratives of community express universal values about creating the conditions for *all* individuals to achieve social or economic progress and for the revitalization of democracy. There is less talk about general social values that children are to ascribe to and more about children constructing knowledge and teachers as partners and collaborators.

The lifelong learner can be thought of as an unfinished cosmopolitan. It is an individuality continually responsible for making choices and innovation as an unending process of life. The future and progress are about making choices and the only thing that is not a choice is choice itself. In educational, health, and crime prevention education in the US and Sweden, for example, the story told the individual of a mode of live of obliged to live with constant changes in society (Popkewitz et al., 2005). Modern schooling, for example, continually links the individual to narratives of social or economic progress and the revitalization of democracy that will bring personal betterment. That individuality is talked about as a lifelong learner who plans one’s biography as continuously solving problems, making choices, and collaborating in “communities of learners.”

The nation does not disappear but is scaled in different ways. Lifelong Learning performs as a particular project to the construction of transnational government and integration with the European Union (Lawn, 2003: 330). The problem-solving life is a governing discourse that travels across national boundaries to recast the educational space into an imagined European community in which knowledge is a key to industrial competitiveness and employment. The image of Europe is of a transnational normativity about cosmopolitan homogeneity. Unlike national identity categories,

its legitimacy appears as not rooted in histories or ancient cultures and territories. The Europe of the lifelong learner is future-oriented whose terms are of universalistic principles about abstract values of human rights, democracy, progress, and equality as everyone's modernity.

What is ignored are the conflicts and divisions through which consensus and peace are celebrated and scaled. The unfinished cosmopolitanism of the lifelong learner is placed in a hierarchy in which the universal moral good of the nation is envisioned as the European Union. Soysal, for example, found a degree of affinity in goals and agencies by actors in different national institutional contexts across the European Union. The emphasis was on a Europe constituted by dialogue, conflict resolution, tolerance, human rights, and intercultural understanding. This is a Europe taken for granted and its project's furtherance was not questioned (Soysal, 2002: 272). Except for the German textbooks that focused on a cosmopolitan universalism that did not mention the nation, the central structures of textbooks linked individual and collective identity with cultural homogeneity that legitimizes the nation-state (Pereyra & Luzón, 2005: 179). Europe is more at its core than in its margins, as in the cases of Turkey and Greece, as the content of education still prioritizes the nation and its chronology (Soysal, 2002: 278).

Social belonging and attachments, however, are not lost. The school and classrooms as communities of learning are sites for recalibrating the political aspirations of the individual with the new assemblies of communities as *the social*. The "barriers" breached across groups in narrations of collaboration join individual agency with the general development of society.

Further, the unfinished cosmopolitanism embodies a fatalism. That fatalism is in its individualizing that speaks of continuous choice, innovation, and flexibility in the face of globalization. Globalization is placed as something that is omnipresent and the given to which the individual needs to develop responsible responses in order to create a better place for the self and ensure "its" progress. This fatalism is continually expressed in policy and research which talk about schools needing to respond to make the Learning Society necessitated by the information society and globalization that have no authors but stand as something that structures who we are and should be.

Comparative Reasoning about Reason: Casting Out Who is not the Unfinished Cosmopolitan

If cosmopolitanism provides a way to think about the hope of the future, its cultural thesis generates principles that order the qualities and characteristics of people who threaten that future. The hope and fears of the child are expressed through reforms and research that are to achieve an egalitarian society where *all* children can learn, *all* children have high achievement, and so on. The *all* expresses the broad political commitment about the unity of society and schools as a positive social institution that serves all segments of society equally. The reforms equally serving all children are not about the unity of the whole. The hope that "*all* children learn", ironically, recognizes and divides the unfinished cosmopolitanism and its "Others."

The efforts for rescue in school reforms bring to bear the double sense of recognition and difference – the fear of not being able to achieve the hope of schooling in making a more equitable society and the fear of the dangers and dangerous populations for the future. The fears have dimensions inside and outside of parameters of inclusion. Contemporary schooling in the industrialized nations, for example, produces “worries” about providing adequate learning for the child who is academically and socially “at-risk.”

The fear of not succeeding with particular children is not only recognition of rescue of those fallen behind. *The recognition of particular populations establishes difference.* The differences are of the qualities and characteristics of dangers and of the dangerous populations – the at-risk child, dysfunctional families, divorced and single parents, juvenile delinquency, drug abuse, and sexual promiscuity, among others. In some countries, the fears are expressed in the discourses about immigrant children, the poor and “needy” who are not doing adequately in schools and whose values and behaviors demand school programs of remediation. The fears are given often through psychological words of difference about lacking self-esteem, the moral disintegration of the family, and inadequate child development that requires rescue, remediation, and counseling. (For a more general discussion of this “property” of modern thought in relation to a European Union study of educational governance and social exclusion, see Popkewitz & Lindblad, 2000.)

The fears appear in the new statistical capacity of European Statistic System (ESS) to produce an inclusive society. The special task force began in 2001 with representatives of five countries (Germany, Netherlands, Portugal, Finland, and UK), European agencies, and two Denmark and Swiss experts (Lawn, 2003: 334). The task force was to identify numerical information and indicators from within European programs about the lifelong learner and the child in need of remediation.

The indicators of success established determinate categories about kinds of people: the “needy,” or the “at-risk” or “disadvantage youth” in schooling (Popkewitz & Lindblad, 2000). In the European context, the child who is not the unfinished cosmopolitan appears in statistical reports as the addicted youth, the teenage mother, and the child of a single parent (mother). These characteristics are placed in relation to ethnicity, race, and other categories of the individual whose difference makes it not possible to ever be of “the average.” The categories have a redemptive quality to social policy, but they also produce divisions and principles that differentiate the “reasonable individual” from those who differentiated as different. The divisions function to qualify and disqualify individuals for action and participation.

A similar process of inclusion and exclusion are embodied in teacher education reforms. The National Commission on Teaching and America’s Future (2003), *No Dream Denied: A Pledge to America’s Children*, for example, signifies the unity of the nation through cosmopolitan values about the inalienable “educational birthright” of *all* children that has an equal place with the constitutional rights of the citizen. The birthright is bound to *being* a lifelong learning in “a culture of continuous learning” in which the competent teachers will emancipate and liberate the universal qualities of human reason and rationality of the child.

The securing of the child’s “birthright” is a double gesture that embodies fears of those who do not “reason” and act as “reasonable people.” The school where “*all* children learn” is a comparative injunctive of fear. It is the fear that not engaging in

the reforms that include will not enable the realization of the dream of the nation. The inclusion of diverse learners is to enable them “to acquire the knowledge, skills, and dispositions that will allow them to succeed” (Hammerness et al., 2005: 390).

A report on the middle school instruction, as well entails double gestures, qualify and disqualify individuals for participation that takes into account developmentally appropriate psychology. Planning teaching should reflect the physical, psychosocial, and cognitive development of young adolescents, inscribes the threats to the moral order of young adolescence who experience increased peer pressure to experiment with tobacco, increased sexual activity and sexually transmitted diseases, teenage pregnancy, alcohol, illegal drugs, and criminality (Manning, 2002: 50–51).

While no longer evoking the earlier Social Question of the city, the question of moral disorders still occupies reforms. The Social Question is transmogrified into the optimism of rescuing and rectifying failures by turning to reforms that recognize and differentiate “targeted populations.” The populations are not placed in the space of *all* children, but to be included yet cast out as dangerous.

Working Toward Comparative Studies of Schooling as a Historical Problem of the Present

Cosmopolitanism is used as an “intellectual tool” to think historically and comparatively about schooling as sites that connect individuality with collective belonging and “homes”. I spoke about cosmopolitanism as cultural theses to consider the principles generated about modes of life in pedagogical policy, reform, research, and pedagogy. I considered, for example, how the categories about the child as a problem-solver, acting in communities, and collaborating are not merely concepts to express policy intentions or altruistic goals of schooling in relation to child empowerment or self-realization. Such concepts are assembled historically and, shaped and fashioned as governing practices in ordering conduct. Further these governing practices of reflection and action link to principles of collective belonging *about* the future citizen of the nation that is scaled today in different ways than previously. The relation of the individual qua citizen of the nation and European “identity” in the European Union is one such example of scaling.

I used the plural, cultural theses, for two overlapping considerations.

First, the plurality is related to cosmopolitanism and processes of abjection. The principles generated about the cosmopolitanism of the child entailed the production of “others,” the child who does not have the qualities and characteristics of “reason to qualify as a ‘reasonable person.’ Those who do not enjoy the status of the subject, but whose lives are circumscribed by the cosmopolitan modes of living are part of the same phenomenon of schooling and not, as in the equity problematic, distinct and separate qualities. The phrase “all” children embodied a comparative instantiation of the unity of the whole from which to establish difference. The subsequent and continual reiteration in policy statements about school reforms about ‘all children will learn’ and that programs ‘accommodate *all* students’ create a space of mystical participation in a common good that, in fact, differentiates and divides. My argument, then, is that the

production of the cosmopolitan child in school reform evokes and enforces its Others” in its principles of inclusion.

Second, the individuality embodied in cosmopolitanism is not merely variations of a single cultural thesis but produced in different assembles, connections, and disconnections. My focus on the cultural thesis of the unfinished cosmopolitanism and processes of abjection, for example, drew primarily on historicizing the principles generated and mutating from northern Protestant European and North American enlightenments. This strategy is to provide historical specificity; yet at different points there were different and diverse cultural theses such as within Dewey’s “traveling” as a conceptual personae. Cosmopolitanism, then, is a historical rather than normative method to explore the generation of principles about modes of life in a broader historical field of comparative studies.

Cosmopolitanism as generating cultural theses is to consider the politics of schooling. That politics lies not in the conventional notions about the allocation of values that dominate political science literatures and school questions about who rules, whose knowledge, and who is ruled. The politics that I speak about is the prior system of reason that classifies, distinguishes, and differentiates the qualities and characteristics of the child who is qualified and disqualified for participation. The universalism given in the cultural theses about the cosmopolitanism of the child provide a seeming transcendent set of values that shreds the provincial and the past. That transcendence is for an inclusive society spoken about in contemporary European and North American policy and research as schooling for “all children.” The “all” is to signify the enlightened unity that transcends human differences. The gesture about the “all” of humanity, however, is not universal but historically and particular. It embodied exclusions: processes of abjection that cast some qualities of people as outside of the spaces of “reason” and inclusion. And it embodied a distrust of democracy itself as participation and collaboration were ordered through shepherds.

Cosmopolitanism, then, is a strategy to historicize the present and explore the cultural theses about modes of life formed and the changing patterns of power embodied in the modern school. The problem is not whether people have good intentions or not, or are reasoning properly. I assume that people have good intentions but different paths to bring happiness and to recognize and to correct those classified as not being able to participate, are marginalized, or excluded. Yet the practices of inclusion are processes of abjection that cannot be considered as Kantian categorical imperatives of reason. The processes of inclusion and abjection are embodied in the very systems of reason through which intention and purpose circulate in the complexity of what is both inside and outside, both rescued and cast out as threats to cosmopolitanism, and thus as the unlivable spaces.

I want to focus some issues that emerge in these considerations for the study of schooling.

First, today’s governing is not one of weaker or stronger state compared to the state operating in the “future of yesterday.” The state is not withering away. There are different cultural and historical spaces where new configurations in governing the self are formed.

Second, the discussion of cultural theses places certain strains on the residual categories of nineteenth- and early twentieth-century theories. Those theories differentiate

the social and the individual; private and public. The discussion of cosmopolitanism points, I believe, to the historical poverty of these distinctions in questions of schooling and pedagogy.

Third, the focus on cultural theses was to recognize the overlapping of cultural, social, political, and economic distinctions in schooling. While it is fashionable to speak of schooling as a reduction to economic categories, reading of school reforms entails no such thing. There is no evidence that there is any relation between schooling and the competences of work except in the general qualities of one's habitus (Meyer & Jepperson, 2000). While it is fashionable to talk about the economic as structuring educational policy and theories of the child, economic theories of work are often psychological theories of the moral and habitus of the worker today; industrial theories are cultural theories of modes of living that relate individuality to leisure as well as work productivity. There is evidence that pedagogical theories are also transported into business theories and practices that instrumentalize work.

Finally, there is a paradox to this argument. The focus on cultural theses about cosmopolitanism in schooling is a comparative historical "tool" to diagnose the system of reason through which principles are generated that differentiate and divide who the child is and who is not that child (Popkewitz, 1991, 2008). The paradox is that to examine the comparative system of reason embodied in schooling while arguing for a method of comparative studies. In one sense, this chapter lives with the blackmail of the Enlightenment's commitments to reason in even its arguing against its modern dogma (see Foucault, 1984).

Notes

1. I use the long nineteenth century to consider uneven historical movements from the late 1700s through the turn of the twentieth century that come together in the making of the modern school and its pedagogy.
2. The notion of citizen is considered historically as the "responsible" individual who is the agent of change in the political community of the nation. Few nations today have government that is based, at least officially, on its population responsible for electing its representative. This notion of participation is related but not necessarily bounded by the ideal types of Republican government and its notions of civil virtue in comparison to that of the notion of subject of the nation. While Sweden and Australia, for example, are not formerly republican forms of government, ideas of civic virtue and democracy do prevail and in this sense, it is appropriate to use the notion of citizen. This historical use of citizen is linked to the function of schooling in the making of child who participates in and feels "belonging" to the nation.
3. This term emerged in work that I did with Jamie Kowalczyk (see, e.g., Kowalczyk & Popkewitz, 2005) and related to Kristeve (1982) although our use was without the psychoanalytic traditions that Kristeve draws on.
4. The production of differences as it relates to urban education is discussed in Popkewitz, 1998b.
5. The following is drawn from Popkewitz (2005), particularly the introduction.

MULTICULTURAL EDUCATION IN A GLOBAL CONTEXT: ADDRESSING THE VARIED PERSPECTIVES AND THEMES

Carl A. Grant and Ayesha Khurshid

We live in a global village shaped by technology that allows us to watch events unfurl in real time even if they are occurring thousands of miles away. Economic market forces are reshaping our world in many ways, changing how and where we live. Since the end of World War II, there have been huge changes in maps of our physical world, as arbitrary political boundaries shift and change and nation states both arise and disappear. Demographic maps continue to change and evolve, as population numbers increase and decrease due to birthrates, war and political and economic emigration, and population characteristics such as age, race, religion, socioeconomic status and ethnicity shift likewise.

As educators committed to multicultural education, we recognise the multiplicity of identities and cultures that exist in our global village and we acknowledge that they are often sources of conflict or foci for controversy. We believe that everyone should enjoy fundamental freedoms for without distinction as to race, sex, language or religion; but we acknowledge that basic human rights still do not exist in some parts of the world. We also know that the very words we use to describe our goals and the tools we use to achieve them remain contested terrain: multiculturalism and multicultural education mean different things in different countries, and the impetuses for acknowledging and advocating them often spring from very different sources.

In some countries, multicultural education is promoted as a means to help students obtain skills for employment in the global society and to educate citizens to accept and affirm human/cultural diversity. In other countries, the idea of multicultural education (and multiculturalism) is seen as a way to address equality issues; and still in other countries it receives a mixed acceptance or it is rejected for various reasons, including a perception that it is a threat to national 'solidarity' (Kanpol & McLaren, 1995; Parekh, 2000).

The reasons why multicultural education has evolved, arrived or been accepted or contested in countries vary. In some, it is a response to demographic changes created by immigration, or it is related to the exclusion of indigenous groups (Bullivant, 1981; Kivisto, 2002; Parekh, 2000). In other countries, it arose from the actions of marginalised groups to achieve equality and equity.

Multicultural education is often seen as a contested space where the issues of diversity, power, oppression and resistance are shaped in the context of citizenship and by the affects of globalisation. A comparative examination of multicultural education reveals

a number of similar themes in different countries. However, a critical analysis of these themes shows that they are multilayered and multifaceted constructs (Banks & Banks, 2004; Kivisto, 2002; May, 1999; Parekh, 2000). It is thus difficult to make sense out of the meaning and impact of multicultural education without first closely examining the historical and social context in which it is situated.

The goal of this chapter is to address the varied perspective and themes of multicultural education as they operate in different countries. We identify idiosyncrasies of apparently homogenous themes in part to show that multicultural education is not a simple concept (e.g. mainly about tolerance) but is complex, multilayered and ever-evolving. In addition, we address the similarities in the struggles of students and teachers for better educational opportunities. Our approach is to identify and juxtapose themes and to discuss how governments, individuals, organisations and events influence attitudes and policies about multicultural education.

Much of the chapter is based on an analysis of the works of educators and researchers from different countries that grew out of the International Symposium on Multicultural Education: Theories and Practices, held in 1997 at National Taiwan Normal University. This conference was then followed by a symposium at the American Education Research Association (AERA) conference in 1998 and then compiled into a book, published in 2001, titled *Global Constructions of Multicultural Education: Theories and Realities* edited by Carl A. Grant and Joy L. Lei. We analyse research on multicultural education from Australia, India, France, Argentina, Taiwan, northern Scandinavia, Brazil, Pakistan, Canada, the United States, Spain, South Africa, Namibia, United Kingdom, Latin America and Chile.

This chapter is informed by a critical and multicultural theoretical framework (Grant & Sleeter, 1985; Sleeter & Bernal, 2004; Sleeter & Grant, 2007). The focus of the chapter is primarily on the role of the government policy at the national level, rather than groups, movements or organisations. This is so because national policies and resources are a major influence on multicultural education, even in those countries that function under a federalist system. That said we do discuss the struggle and influence of teachers, students, parents and other social actors for multicultural education.

We will use the following organisation to address the varied perspectives and themes of multicultural education as they operate in different countries: (1) multicultural education viewed as a problem rather than a goal or solution; (2) multicultural education and the 'other'; (3) inspiring events for and opposition to multicultural education; (4) the focus of multicultural education in different countries; (5) implementing multicultural education policies; (6) teachers' roles and participation in multicultural education; and (7) globalisation and multicultural education. By no means is this chapter intended to be exhaustive, or even comprehensive. Rather, we hope that the analysis will inspire increased attention to the subject and spur additional scholarly research and discussion.

Multicultural Education Viewed as a Problem

Multicultural education is considered a problem in most countries. It is often presented as a social and financial burden on the citizens of a country because it is presented as a tool for educating immigrant children, who have come with different cultural traditions

and languages (Glenn, 1996; Pitkanen et al., 2002; United State Accounting Office, GAO, 2004). Australia and Canada are two countries where multicultural education policies are connected to immigrants. In the United States, however, multicultural education is seen as a product of the 1960s Civil Rights Movements (Banks, 2004; Grant & Ladson-Billings, 1999) and is therefore perceived as a new crusade against racism. Nonetheless, multicultural education is often viewed as an educational frill in the United States, and, as such is often underfunded or ignored when budgets are compiled.

In France multicultural is a non-problem problem. It is considered an antithesis of the republican principles of equality, enlightenment and freedom. There is no policy on multicultural education because France's official assimilation policy requires everyone to adopt and follow traditional French norms and ideology. France is a special case, because while some other countries use assimilation ideology to guide their multicultural education policies, France is explicit in its argument that multiple identities must melt into the French culture (Dussel, 2001; Glenn, 1996; Seijuq, 1997).

Multicultural Education and the 'Other'

An important feature of multicultural education in some countries is a focus on marginalised groups that have been excluded from mainstream society because of their race, ethnicity, birthplace and language (Kivisto, 2002; Moodley, 2004; Parekh, 2000). Class is often considered along with these factors, whereas gender is often marginalised because of the ideology of the country.

There is an unstated or stated idea – depending on the country – that multicultural education is about the Other; and the Other is most often a member of a racial/ethnic minority, either from an indigenous group or part of an immigrant population. A striking example of this is the “othering” of the Sámi people. The Sami nation's boundaries overlap the national borders of Sweden, Norway and Finland. Sweden established separate schools for Sámi people to protect them from the ‘evils of civilisation’. Norway and Finland, in contrast, established assimilation policies which allowed Sámi students to attend mixed schools, but placed a ban on the use of Sámi language in schools. The lumping together of people based on their cultural heritage or language into an artificially constructed Other ignores the multilayered and multifaceted diversity inherent within and across the groups when developing multicultural education and constructing immigrant policies (Kivisto, 2002; Parekh, 2000).

Inspiring Events for and Opposition to Multicultural Education

The presence or absence of policies about multicultural education in any country is inherently connected to historical events and social relationships in that country (Seijuq, 1997). Such events and relationship may create top-down or bottom-up initiatives for multicultural education. In Australia, for example, issues over immigration, including language and birthplace helped to bring about the creation and adoption of multicultural policies (Smolicz & Secombe, 2003; Sturman, 1985). In the United States, multicultural education grew out of bottom-up efforts. It is primarily a product of the 1960s Civil Rights Movement for racial equality (Banks, 2004; Grant,

& Ladson-Billings, 1999). The bottom-up and top-down peculiarity reinforces the importance of connecting the objectives and implementation of multicultural education to its origins.

Opposition to multicultural education is predicated upon different reasons and usually comes from different groups of actors. In the United States, for instance, much of the recent opposition comes from some people who believe that issues of equality were resolved during the Civil Rights movements of the 1960s and 1970s that focused on racial equality, gender equality and the acceptance of gays and lesbians in society. In contrast, critical scholars believe that multicultural education is a weak approach to effecting social justice such as eliminating the structural inequality they believe still exists in the United States (Sleeter, 1995).

The opposition to multicultural education in France is at the official governmental level. France does not see itself as a multicultural society, despite a significant presence of minority populations. The basic premise of French nationhood is that there can be no group affiliation more powerful than the nation. The official ideology considers schools as a privileged place where the goals of equality can be achieved through structures of centralisation and homogenisation (Dussel, 2001; Glenn, 1996, Seijuq, 1997). This ideology remained largely unchallenged until the veil affair when an official policy introduced in 1994 distinguished and banned only hijabs as religious symbol in schools. The debate over this issue was presented as a battle between universalism/democracy ('France') and integrism/fundamentalism ('the Muslims and the ghost of 'Iran') (Dussel, 2001; Giry, 2006).

Opponents to multicultural education in Argentina consider it a North American discourse. However, the nature and content of this opposition is different from the opposition in France. Opposition to multicultural education in Argentina has grass-roots support and is led by working class students and teachers (Glenn, 1996; Dussel, 2001). This movement emerged as a result of the education reform supported by the World Bank (Dussel, 2001). These reforms replaced the earlier idea of social equity in schools with compensatory programmes that provided lunch snacks and special aid to poor children. These compensatory programmes in Argentina differentiated students on the basis of their parents' ability to obtain resources. These reforms not only introduced competition amongst schools over scarce resources but also resulted in the closing down of many schools because of insufficient funding. As a result, working class teachers and students initiated an opposition movement to resist their expulsion from schools (Dussel, 2001).

The Focus of Multicultural Education

Historical context, as we noted, plays a central role in defining the focus of multicultural education in any country as well as the focus on the *Other*. Yet, there seems to be a somewhat common approach to multicultural education in many countries, particularly Western countries. For example, multicultural education in the United States and Australia has arisen from different circumstances. However, both countries have approached the implementation of multicultural education in a similar fashion.

To illustrate this point, we have divided the history of multicultural education in different countries into three broad categories or phases. These phases are not exhaustive in reporting all that took place in an approach in every country, but they allow us to see the general pattern and trend that has been followed in most of the countries.

First phase: The first phase includes using assimilation policies at schools, which encourage and/or insist immigrant and minority group members adopt dominant customs, habits and ways of thinking and acting. In most countries we examined, multicultural education is about the endorsement of these assimilation policies to control ethnic and racial differences. Examples include students of colour adhering to white middle-class teaching and learning ideologies in the United States and the banning of Sami language in mixed schools in Finland and Norway. Assimilation policies in both countries were ineffective in that they failed to eliminate racism and discrimination against minority students. Nor did these policies improve the academic performance of minority students.

Second phase: The second phase is marked by the adoption of weak multicultural education practices such as the acknowledgement of minority groups' signs and symbols of culture and celebrating their culture with food fairs and festivals. Some reorganisation of diversity curriculum is included in the curriculum and some teachers may espouse a culturally relevant pedagogy, but most of these efforts are superficial (Sleeter & Grant, 2007). This is especially so in Australia, United Kingdom, Canada and Chile (Grant & Lei, 2001). The ideology guiding this phase is based on the idea that ethnic and racial minorities have a legitimate culture that should be celebrated. An interesting observation of this phrase is that some of the neo-liberals in the countries share the belief – articulated in Gordon Allport's contact theory – that contact with the Other will counter issues of racism, prejudice, ethnocentrism and xenophobia.

Our assessment of this phrase is that official (and unofficial) multicultural education policies in most countries including the United Kingdom, Chile, Canada and Australia remain mainly at the level of acknowledging diverse cultures, but not affirming diversity and taking power into account. While the guiding ideology acknowledges that ethnic and racial minorities have a legitimate culture, it still promotes assimilation, and mainly advocates tolerance between and among groups. Carl E. James (2001), for example, points out that policy makers in Canada see multicultural education as merely 'difference' and they base educational policy on an idea of 'cultural democracy' that assumes that all the norms, traditions, institutions, laws and policies are culturally neutral, and each and every citizen should be able to equally avail of them without any barriers.

James goes on to argue that although multicultural education programmes include instruction in languages other than English and French; the study of 'foreign' cultures, heritage studies and literature of different groups, the policies and programmes neither address nor acknowledge the dominance of Anglo-Celtic Canadians as an ethno-racial group and the construction of those of English and French heritage as the 'real' Canadians. In addition, he contends that within these policies the 'cultural other' is constructed as exotic and the difference is made out to be 'foreign'. These policies, he asserts, overlook the issues of colonisation, power and resistance that shape the lives and realities of the students in the classroom.

Third phase: The third phase within the multicultural education movement is marked with tension between anti-racist/critical multiculturalism advocates and traditional multicultural education advocates. Critical multiculturalism advocates argue that traditional multicultural education does not address structural inequality in schools and society (Sleeter, 1995). Harry Tomlinson (2001) argues that traditional multiculturalism focuses exclusively on culture and assumes that everyone starts on an equal base. He concludes that these policies, despite good intentions, have put minority students like Black children at a further disadvantage in the United Kingdom. A number of educators and researchers from different countries present anti-racist/critical multiculturalism as an alternative to traditional multicultural education. The anti-racist/critical multicultural perspective seeks to provide students with a critical understanding of their social position and experiences as structurally influenced by unequal social relations in school and society. This perspective is strongly associated with the idea and possibility of social justice, equality and economic democracy. It also identifies the challenges inherent in the notion of 'difference' as well as the close relatedness of the concept of difference with capitalist exploitation, profit and individual gains. Thus anti-racist/critical multiculturalism articulates that it is possible to examine critically the issues of power and racism while supporting the cultural activities. The tensions within the multicultural education movement are reflected in the debate around this issue in South Africa. Jeremy Sarkin (2001) explains:

The Black Consciousness movement endorses the anti-racist approach by arguing that multicultural education promotes differences by thinking about people and culture in specific ways instead of creating national unity in the post-apartheid South Africa. They assert that culture cannot form the foundation of education policy since it has been distorted by racism and capitalism. On the other hand, advocates for the multicultural education perspective argue that multiculturalism arose out of the struggles of people to have equal and desegregated schools. They also believe that multicultural education can lead to national reconciliation through implementing a curriculum, which values diversity, tolerance and appreciation of cultural differences. This approach, they believe, can help students to manage cultural differences productively without resorting to violence or isolationism.

Joy Lei and Carl Grant (2001) define the tensions within the United States multicultural education movement in terms of the goals of equity and equality. The equity perspective advocates an active fight to resolve the racial crisis and other forms of oppression in the United States, whereas the equality perspective focuses on recognising and valuing various cultures and devotes less attention to race, racism and other forms of oppression.

An additional feature of the third phase calls attention not only to the debate around diverse approaches to multicultural education, but also to the gaps between theoretical conceptions and practical implementation of multicultural education. Lei and Grant argue that multicultural education is much more difficult to implement than to define. Moreover, they contend it is easier to espouse the equality perspective by committing to implementing equal and fair representation of people of colour, women and people with disabilities than to espouse the equity perspective because the latter demands making substantial policy and implementation changes in the entire field of education, in order to eliminate racist, sexist, Eurocentric, classist, heterosexist and able-ist policies and practices.

This argument leads to the next section, which outlines the issues related to the implementation of multicultural education policies, which often focuses on the equality perspective. We report that the mere presence of a multicultural education policy cannot ensure a positive result on behalf of equity and social justice.

Implementing Multicultural Education Policy

Both the introduction and implementation of multicultural education have faced challenges in most, if not all, countries. Some of the challenges are pertinent to the exclusive focus on multicultural education, e.g., the Aboriginal population in Canada considers the multicultural education policy irrelevant to them since this policy makes no reference to their language or culture. However, there are also a number of other implementation challenges, such as dualisation of schools as well as a lack of structural support (e.g. funding) at schools to carry out multicultural education policies.

Dualisation of schools: Sveta Dave Chakravarty (2001) argues that the main objective of multicultural education in India is to bring about an effective education, which is accessible to all who attend the common school system. Although the constitution of India provides for protection of different minority groups, the educational system of India continues to perpetuate inequities which have a long history in the country. The centuries-old caste system, which confined education to people from higher castes, and the British colonial system, which encouraged only a small segment of society to acquire education, are still in place. India has a multi-tiered educational system: private schools, English medium school and public schools.

Mainly children from the privileged section of the society attend the private schools or the English medium schools, where they are prepared for elite jobs in society. Children from the most disadvantaged sections of the society are only allowed to attend public schools, where they are trained to memorise and recall information instead of analysing and critiquing information (Chakravarty, 2001; Sinha, 1997).

Chakravarty (2001) contends that although the Indian government has taken some important initiatives to bring about equal access to education, most of these initiatives fail because of bad management and/or the way the centralised bureaucratic system operates. Policies are implemented with an assumption that students across the country will have uniform levels of achievement if the same content is delivered in the same way. One initiative by the government includes expanding the number of primary and secondary schools and increasing the enrolment rate. Another initiative is the government reserve seats for students from marginalised groups in higher education institutions and in the elite civil services. These initiatives, and others, however, have not resolved the problems that the many students from marginalised groups face regarding access to high-quality primary education as well as entrance into and completing higher education. Chakravarty argues that factors such as high dropout rate and the Indian multi-tiered educational system are contributing to the school problem in India. In short, she argues that despite the presence of affirmative action policies at the higher education level, the education system has largely been unsuccessful in ensuring equal access to all sections of the society. The main goal of multicultural education in India,

Chakravarty believes, should not only be to attract and retain children from all backgrounds but also to provide them quality education.

Carlos Alberto Torres (2001) presents a similar case for Latin America. Torres argues that schools prepare two groups of citizens. The first group consists of students who are privileged in that they may exercise their political and social rights not only through voting but also through the networks of power. These students often come from privileged sections of society. The second group is students who are considered 'dispensable'. This group faces political isolation, fragmentation and economic disparity. They are citizens who often come from marginalised backgrounds; and some of their marginalisation comes from the way they are constructed in media. The neo-liberal thinking that people are free to exercise their right of representation through voting, and thereby have gained equality in schools and other social institutions is refuted by the striking disparities in not only the quality of education that these two groups receive, but also their educational outcome. The gender, racial and class hierarchies embedded in the social and political structures do not allow the 'dispensable' citizens to use education to improve their social and political position in the society.

In South Africa according to Sarkin (2001) the 1994 post-apartheid legislation ended the official segregation of schools and promised to provide free and compulsory education for everyone in order that they might be able to overcome past racial inequality in schools and society. However, this legislation has yet to be successfully implemented, since it is only the White schools that have been integrated. Black schools still face issues of overcrowding, under-qualified teaching staff and inadequate funding.

Structural Support to Implement Multicultural Education Policies

There are a number of countries that officially acknowledge the importance of introducing policies and programmes to support the academic and social success of students from marginalised sections. However, gaps often exist between official education policy, which espouse the need of multicultural education, and the procedures and practices within schools. This is sometimes the result of lack of or minimal government enforcement of policies.

The United Kingdom presents an example where the issues associated with racial inequality are given some attention in curriculum, but issues of racial inequality are not comprehensively addressed in the overall educational reform programme because, in part, the education authority does little to enforce policies and practices that directly deal with racial equality. Instead, sometimes education authorities offer up programmes that they argue will better prepare students to get jobs, leaving aside attention to racial inequalities. Harry Tomlinson (2001) argues that many of the educational reform that advocated forging relationships with community and parents, in practice diverted attention from race issues by introducing new curriculum and national assessment procedures, local management of schools and open enrolment. He contends that, despite an explicit acknowledgement of multicultural education, these reform efforts did not create structural support to address and resolve the issues of racial inequality.

Germany, Italy and Switzerland are some of the other European countries that support the right of racial and ethnic minorities to retain their culture and language in

principle, but have not introduced effective programmes, enforcement mechanisms to translate educational policies into a practice, or encouraged teachers to support multicultural education. Cristina Alleman-Ghionda (2001) argues that a gap exists between the official pronouncement of support for minority rights and the programmes and practices in schools which instead adhere to the principles assimilation. Alleman-Ghionda contends that a challenge to the implementation of multicultural/intercultural policies has to do with convincing teachers to take recommendations for multicultural education seriously. She argues that it is not possible to translate official policy into practice without the consent and active participation of teachers. Further, Alleman-Ghionda contends multicultural and/or intercultural policies have not been successful in challenging the influence of the mainstream idea of 'one region, one culture, one language'.

Multicultural Education: Teachers' Role and Participation

The preparation and participation of teachers are critical dimensions of multicultural education. Education scholars argue that teacher preparation is key to multicultural education as well as the key to working with students who come from diverse socio-cultural, racial and ethnic minority groups (Cochran-Smith, 1991; Grant & Gillette, 2006; Grant & Sleeter, 2007; Ladson-Billings, 2000; Nieto, 2000; Sleeter, 2001). These scholars assert that teacher preparation should engage in critical pedagogy that should prepare teachers to build on the cultural difference of students, as well as teach them how to develop and establish positive relationships between teachers, parents and other community members.

In addition, these scholars presently contend that most teacher education programmes do not prepare teachers to be critical educators. Miguel Santos-Rego and Servando Perez-Dominguez (2001) argue that teacher preparation programmes in Spain are isolated and fragmented because of a lack of specific regulations. They contend that universities are given self-rule to prepare teachers according to their economic autonomy. By this, Miguel Santos-Rego and Servando Perez-Dominguez mean that if the university has funds available to introduce multicultural education and has professors who are willing to work in the area of multicultural education, they may proceed. If not, they cannot proceed.

Teachers as individuals and as a group do not have the power (and have not shown the desire to) to demand staff development in multicultural education. The limited collective participation of teachers in policy making becomes a significant factor in their lack of willingness to implement multicultural education programmes (Ladson-Billings, 2000). In Brazil, where the official ideology is 'racial democracy', the school curriculum neither acknowledges the diversity of racial groups, nor the existence of racial inequalities in the society. Here, although there is racial prejudice and discrimination in the public schools, teachers refuse to admit that they notice the race of their students. However, schools and teachers contend that Dark and Black students should 'whiten' themselves in order to be successful at schools (Hypolito, 2001).

In Argentina, teachers have spearheaded a movement which opposes multicultural education and describes it as 'a North American discourse'. These teachers, however,

it should be noted oppose educational reforms that push students and teachers out of schools, close schools because of lack of funding and question the goals and curricula of schools that receive support from the World Bank. The premise for this movement is that current educational reforms have replaced the idea of social equity with differentiating compensatory programmes. In addition, the teachers and students are resisting neo-liberal policies that support the privatisation of schools and the reduction of schools in the public sector.

Globalisation and Multicultural Education

Educational reforms in a number of countries have turned schools into private enterprises in the name of market competition (Edwards & Usher, 2000). Many countries have a growing concern about job loss due to international market competition and focus on the need to prepare students for a global market-based economy. The impact of globalisation has been particularly devastating for low-income people in 'third world' countries. For example, in Pakistan the education system was privatised in hopes of producing students with skills needed in the global economy. This privatisation, however, has created even more income disparity between the poor and the rich than existed before it was enacted.

This is because, although the education system in the past was not particularly successful in serving the marginalised sections of the society, the state-subsidised schooling at all levels did provide some opportunities to people from low-income groups to enter into professional colleges; and the state-run higher education institutions also provided quota for students from different sections of the society. However, these provisions and other opportunities are being completely wiped out in the name of educational reforms (Khurshid, 2007).

Tomlinson (2001) argues that the marketisation of schools in the United Kingdom resulted in a dual process of taking the power from schools and placing it in the hands of parents at the local level, who often are more interested in examination results than social issues.

Cahill (2001) argues that pro-globalisation educational policies in Australia have been marked by a popular support for racialised policies towards immigrants and indigenous groups. He explains that these racialised policies are supported by the downwardly mobile groups in both urban and rural contexts as well as by the middle-class. This is because people of the urban and rural working class who lost jobs because of the effects of globalisation do not want to compete with immigrant and indigenous people for existing jobs. The middle-class supports these racialised policies because they fear losing their jobs to immigrants. Cahill points out that a number of these racialised policies have cut services to immigrants and have also negatively affected multicultural education in schools including downgrading the focus on ESL in the education system.

As we look across the different countries, it is clear that globalisation has, to some extent, resulted in further marginalisation of many minority students in schools. The reduced role of the national governments in education due to such reform efforts as privatisation of schools has not only led to limited support for the disadvantaged groups, but has further jeopardised the well-being of the group. In addition, the effects

of globalisation have increased competition over scarce resources, which has in some cases resulted in the rise of anti-immigrant movements.

Conclusion

This chapter is a reading and discussion of the research on multicultural education in different nation states. We have used this literature to identify the common themes. We conclude that multicultural education in the global context is multifaceted and often constructed on an unequal landscape where power relations are very active. There are a number of themes that are common to different countries, such as using multicultural education to support assimilation policy. In addition, we conclude that it is the power of the people who engage in the struggles for equity and equality that has pushed establishments in different countries to introduce and implement multicultural education policies. At the same time, we argue, that, based on the literature reporting on multicultural education, much remains to be done if the goals of equality and equity are to be accomplished.

Finally, it is clear that while it is advantageous to learn from the history and experiences of the multicultural education movements in different countries, it is, nevertheless a dangerous practice to adopt and transport a model of multicultural education from one country to another. That said, the recognition and analysis of similar themes can serve to help build international connections between scholars and educators throughout our global village.

INTERNATIONAL DEVELOPMENT EDUCATION

Nancy Kendall

From moralizing calls for its end (Esteva, 1992), to critiques of its discourses and practices (Samoff, 1999), to recent arguments for the potential necessity of its continuance (Ferguson, 2002), the effects and goodness of the field of international development (education) has been debated for decades. Despite these critiques, it has witnessed a renaissance in the past 15 years. This chapter describes the history of the field of international development education, examines current practices and trends, and discusses emerging questions for the field. It concludes that there are both legitimate concerns about the effects of international development education practices and reason for cautious optimism about some current practices, particularly those that take account of past critiques and attempt to restructure the relations and activities undertaken in the name of development education. International development education continues, however, to rely primarily on out-of-date discourses, rationales for its existence, and ways of dividing up the world; without addressing these issues in an inclusive manner, international development education funding, policies, and programming will rarely support positive change, will in some cases make things worse, and will lose its relevance and widespread support. Before continuing, I briefly discuss the terms “international,” “development,” and “education”.

Development

The vocabulary and concepts employed in the international development arena are highly contested, as they reflect, represent, and some would argue (re)create underlying tensions concerning power and authority. The first arena of dispute is the word “development” itself, which, as Grillo and Stirrat (1997) note, is often placed in quotations by researchers to highlight various problematics. International development is generally understood to encompass goodwill efforts by richer (industrialized, “modern”) states to improve the lives of people in poorer (agrarian, “backwards,” or “primitive”) states. This general definition draws on a number of historically Western concepts (linear progress, the nation-state, individualism, state-sponsored mass schooling) that form the core concerns of many critiques, such as the continued assumption that there is a unitary and linear path of “development” upon which all people and states must tread in order to enjoy the good life (Kothari, 2005). For other critics, the central problematic is the simultaneous creation of under- or undeveloped people and places through the

construction of developed ones (Escobar, 1995). Still others focus on the asymmetrical relations of power and authority created through development discourses and practices (Samoff, 1999).

Many of these critiques highlight a central paradox: the concept of international development seems superficially unimpeachable. In practice, however, international development efforts are judged failures for many reasons and with great consistency. Despite this, they continue to serve as the primary official global approach to addressing issues of equity, progress, and our connections as fellow humans. How are we to understand what it is, then, that development discourses, practices, and resources do to people and places around the world? How are we to judge whether they help or hinder? As Rist (1997: 1) states:

[T]he strength of ‘development’ discourse comes of its power to seduce, in every sense of the term. . . . How could one possibly resist the idea that there is a way of eliminating the poverty by which one is so troubled? How dare one think, at the same time, that the cure might worsen the ill which one wishes to combat? . . . How are we to explain the whole phenomenon, which mobilizes not only the hopes of millions but also sizeable financial resources, while appearing to recede like the horizon just as you think you are approaching it?

The history of the concept of “development” is a long one (Fagerlind & Saha, 1989); it has been used to indicate the current set of activities, ideas, and relationships termed “international development” for only about the past 60 years. The current definition crystallized in the post-World War II era as a group of so-called modern states (primarily Western European states and the United States, and later Canada and Japan) created institutions (such as the International Development Association and UNESCO), ideational statements (such as the UN Declaration on Human Rights), and professional venues and organizations (such as the UNESCO regional education meetings and the US-based Comparative Education Society) that supported an array of activities designed to learn about, support, and improve life, including through education, in so-called developing states.

The history of this term is central to understanding its current use. Perhaps the most important influences on current conceptualizations of international development (education) stem from the nineteenth century Enlightenment period and the taken-for-granted goodness of particular models of modernity, civilization, Enlightenment, truth, progress, and schooling that developed in Europe and the United States during this time (Meyer et al., 1977; Meyer, 2000). These models continue to heavily influence conceptualizations of international development and development education, from the actors and institutions considered legitimate (e.g. states), to the concepts of comparison and ranking that drive conceptualizations of neediness and its causes (Chabbot, 2003; Manzo, 1991).

Rist’s *The history of development: From Western origins to global faith* (1997) provides an excellent overview of historical and current development paradigms and points to some important considerations about current definitions. First, most are self-referential—that is, they depend upon the definition of progress, justice, desired

lifestyle, and forth held by the individual—and thus are problematic as a shared construct (Rist, 1997). Poerksen's (1985) notion of “plastic” words may be of great utility in understanding the power and weaknesses of current definitions of development. Plastic words are those that began as words with distinct meanings in common parlance, that were then expanded to be used in more generalized scientific discourse, and finally were taken up in general and technocratic language in such a manner that their definition is almost infinitely malleable by individual speakers. “Development” is such a word, and its strengths and weaknesses lie at least in part in the ability of individuals and organizations to fill it with their desired meanings.

Second, which definitions of development education come to dominate is a reflection not of a singular reality, but instead of the relations of power and authority that shape the voices heard and their effect on the development imaginary. Current definitions generally begin with the ethical question of how to make sense of, and correct, inequalities in wealth and life opportunities around the world and the suffering that is experienced by the world's poorest people and states. International development aid, focused on poverty reduction, is the answer of the world's rich to this problem (Collier & Dollar, 2000). What, though, constitutes “poverty,” acceptable levels of inequality, or acceptable levels of development aid? These are heavily debated constructs for which the world's richest usually set the terms of engagement; so, for example, the current definition of extreme poverty used by most international development organizations is people living on less than US\$1 a day, and the OECD's member states have set the goal of having each state provide 0.7% of their annual budget for international development funding.

Third, the definitions used by most of the powerful actors and institutions in the international development arena center economic discourses and indicators of progress, survival, equity, and justice. Development, poverty, and equity are still generally measured first and foremost in economic terms (e.g., growth in GDP per capita; growth in the creation of formal labor market jobs; access to “modern” resources such as hospitals or electricity). The centrality of economic imaginaries and rationales (from education as human capital development to people as “homo economicus”) and the discipline of economics in the field of international development is an important factor in explaining why alternative development imaginaries (political, cultural, social, religious, etc.) have failed to gain much traction in the international development arena (Easton & Klees, 1992). Despite the historical role of education systems as (re)producers of political, cultural, and social relations and generational transmissions, not only of productive laborers, this is true even in the development education arena. Early works such as Schultz's 1953 *The Economic Value of Education* and Balogh's 1966 *The Economics of Poverty*, and later rate-of-return studies (e.g., Psacharopoulos, 1985) helped reposition education in relation to models of economic growth and development (Schultz, 1953; Balogh, 1966).

Although there have been challenges to the centrality of economic measures of development (e.g., Bhutan's Gross Happiness Index, which purports to present an alternate model of human development rooted in Buddhist philosophy), these alternatives have seldom mounted significant challenges to the presuppositions

embedded in mainstream development definitions. They have not addressed the issue of defining development by defining its desired outcomes (thus ignoring the problematic “black box” of development practices and relations), nor the significant issue that the process by which alternate models and measures of development have been created has not generally significantly expand the circle of people and institutions that have power to determine what alternative measures of development might be.

The relative stability of the term “development” thus reflects continued general agreement amongst powerful actors and institutions around the world on the shape and scope of the international development arena:

- On the nineteenth century model of modernity that underlies it (Manzo, 1991)
- On the centrality of economic models in which “homo economicus,” the state, and more recently the market are the central actors in educational rationales and processes (Resnik, 2006)
- On what the state’s educational endeavor should constitute (mass school-based primary education, not initiation ceremonies) (United Nations, 2005)
- On the types of actors and institutions involved in the contemporary field (e.g., states and non-governmental organizations) (Federal Ministry for Economic Cooperation and Development, 2007)
- On the types of exchanges of money, goods, services, and other resources that constitute valid “development” support (loans, grants, products, technical assistance to less affluent governments in exchange for adopting certain conditionalities and hiring and buying practices that favor more affluent states, but not “corrupt” practices such as bribes to public and private institutions) (Walliser, 2004)

More serious debate and destabilization has occurred in the terms used to describe relations among actors and institutions in the development arena. In much of the official literature produced by affluent bilateral (USAID, DfID, CIDA, NORRAD, JICA, and GTZ) and multilateral (the UN, the World Bank, the IMF, and the WTO) organizations, these organizations are referred to as “donors” of “foreign aid” or “overseas development assistance.” The states receiving development funds are referred to as “less developed,” “underdeveloped,” or “developing” states and “aid recipients.” There have been a number of thoughtful and serious critiques of these terms, which create the appearance that particular states and organizations (largely European states, the United States, and Japan) are donating resources to less affluent and more needy recipient states. Perhaps the simplest critique is that the vast majority of international foreign aid funding returns directly to the “donating” state. For example, a great deal of aid from countries is tied aid—that is, the money must be used by recipient governments to purchase “donor” government products. So, for example, the Canadian International Development Agency (CIDA) provides resources for a Ministry of Education to print and distribute textbooks to all government-sponsored schools in a country, but the printing must be done by a Canadian publisher.

More seriously, the concept of “donation” usually connotes one who gives or contributes to a charitable cause. In contrast, many argue that international development

funding is more often given for geopolitical gain, to maintain or foster neocolonial relations, or to spend out so-called donor organizations' funds without regards to the needs of the so-called recipient (Tilak, 1988; Schraeder et al., 1998; Lumsdaine, 1993). Likewise, there is extensive evidence (Cornia et al., 1987; Sparr, 1994) of the damage to poor populations, or at a minimum the lack of "development," that has resulted from many poor states floating their currencies, reconceptualizing education as a tradable commodity, privatizing industries such as government printing presses, and shrinking civil service positions and salaries (Alderman et al., 1992); yet these remain popular neoliberal international development education conditionalities and reforms.

Still another critique of the donor/recipient discourse has arisen in response to evidence that the end result of many reforms aimed at developing so-called recipient states has been to open up their economies to greater exploitation by "donors" by, for example, lowering the price of the goods they export or the salaries that they can pay (Sagasti & Alcalde, 1999; Rankin, 2001). This creates a situation in which the so-called donor states become recipients of people, goods, and other resources from the so-called recipient states. In this manner, the true recipients are the states and institutions that supposedly "donate" aid.

Lastly, for development funding given as loans instead of grants, "donor" states and "aid" organizations have made more money in interest from "recipient" states than those states have received in initial capital (Jubilee USA Network, 2005). In this sense, again, the traditional understandings of the words "donor" and "recipient" may be contrary to, or certainly not straightforwardly related to, common usage.

Despite these cogent arguments that destabilize the donor/recipient binary assumed in international development relations and discourse, these terms remain in general use, partly because they have been institutionalized in common parlance, partly because they reflect the development imaginary that is favored by the most powerful actors and institutions in the arena, and partly because other terms put forward as alternatives (North/South, industrialized/industrializing, rich/poor) are generally themselves open to similar contestation. For example, the geographic binary North/South can be useful in discussing which states and non-governmental organizations are generally poorer and which are richer in the world. There are, however, important inaccuracies in the geographical divide, such as Australia in the "South," the Caribbean in the "North," and a growing number of states such as India and Kuwait that now embody what would traditionally be considered aspects of both "Northern" and "Southern" states. All of these binary labels, in fact, assume and fix the focus of developmentalist debates on states at a time when divisions between rich and poor, "North" and "South" are as great or greater within countries as across them, thus concealing the issue of how inequality and poverty affect "Northern" geographical spaces as well as "Southern," and how people, groups, and development-like resources flow within and across state boundaries. In practice, then, no set of binary terms can do justice to these complex relations and resource flows, yet the terms remain in use as shorthand that may in fact reinscribe the central problematics in the development arena.

Education

In contrast to the plasticity and contestation of the term “development,” the “education” concept in use in the international development education arena has been generally fixed since the inception of the field, and has become more so over the past 15 years. Although other models of education have predominated throughout the world’s history, it is possible to argue for a near-hegemonic understanding of and belief in formal, Western-style, state-provided, mass schooling as constituting “education” (for development) in the twenty-first century. This hegemonic conception has its roots in the Prussian mass education system, which was adopted throughout Europe and the United States over the course of the nineteenth and twentieth centuries and was promulgated by many ex-colonies in the post-independence period (Ramirez & Boli, 1987). This model of formal schooling became the focus of international development resources following the 1990 World Conference on Education for All (WCEFA); has been inscribed in international development frameworks such as the Millennium Development Goals; and drives the shape and scope of resources made available to less affluent states through the international development education process.

This model of education, generally speaking, entails support for mass, standardized, state-provided, formal schooling that, in its appropriate form, includes children learning (primarily from adults), about “high-stakes” academic subjects (reading, writing, arithmetic, science), on a fixed schedule, in an indoor setting that includes particular features (desks, chairs, chalkboards, written teaching and learning materials). As with models of international development, there is an imagined, linear educational progression from informal, family-provided education concerning daily tasks (such as survival skills learned by hunter-gatherer children from their parents), through more formalized educational experiences organized by larger bodies (such as initiation ceremonies or trade apprenticeship systems), to “modern” schooling systems.

The international development model of education posits that mass, state-sponsored schooling is: (1) central to the creation of a “modern” nation-state; (2) central to the development of “modern” workers and families; and, thus (3) central to a state’s “modern” economic growth and international acceptance. This general conceptualization of education and development has received critical attention since its inception, but has yet to be significantly challenged.

International

As with “development” and “education,” the term “international” has historically taken on a particular set of meanings in the international development education arena. The concepts of development and of mass education described above rest on the centrality of a particular model of the nation-state that arose in Europe in the eighteenth century and now dominates maps and our imaginaries alike (Meyer, 2000; Ferguson, 2002). For the purposes of this chapter, it is important only to note that the term “international” traditionally refers to interstate affairs and relations. The majority of international

development resources continue to be directed to official state governments, although there has been a shift since the late 1980s towards increased funding of non-governmental organizations (NGOs). In the post-World War II era, it was the sovereign state that was given the right to control the natural and human resources within its boundaries, and the responsibility to fulfil the universal rights (such as for education) of its citizens. Thus, the state had both the right to inculcate its values in its citizens through education, and the responsibility to provide them with such basic services as were deemed to be universal by the UN and its constituent state members. State boundaries around the world reflect everything from wars, genocide, and colonial relations, to topographic divides and historical compromises. The interest and capacity of various states to provide equal resources to all citizens varies just as much as the historical foundations of mapped boundaries. Yet in the eyes of the global community, by the end of the 1960s, most of the world had been divided into sovereign states, each regardless of its size, resources, or propensities, now viewed as the equal of all other states.

As global economic, political, and social relations have shifted, so too has the utility of understanding the world as constituted by sovereign states. From regional economic organizations to intense internal divisions, from NGOs to transnational communities, from rebel groups that control vast swathes of land to transnational investors that can collapse national economies in days, from HIV to global climate change, the bodies and forces that govern people's daily actions and play a role in determining their opportunities for mobility, survival, and thriving differ in their shape, scope, and imaginaries from 60 years ago. Nevertheless, with the exception of increased discussion about the roles of NGOs and private organizations in educational provision (Archer, 1994; Mundy & Murphy, 2001), the field of international development education has not responded significantly to these changes. Current state divisions and international conceptions of state sovereignty fundamentally affect the ability of development efforts to identify and address global, regional, and "local" inequities; however, without destabilizing some of the assumptions currently made about national versus cross- and transnational issues, many inequities conceptualized as state development issues cannot be addressed by international development efforts (Ferguson, 2006).

Below, I review the history of the field of international development education since the 1950s, paying particular attention to the actors and institutions involved in the arena, changing ideas about what constitutes good development education practices, and the critiques that have been levelled against these practices. As will be noted, there is a certain cyclical and fickle nature to development discourse and practices: if an idea, such as universal primary education, gains momentum, the momentum is likely to be lost just as widespread agreement is reached, only to reappear a decade or two later in a slightly revised form as the brand new panacea for the constant refrain that development education. This cycle is likewise visible in education's positioning in the broader international development arena.

1950s and 1960s

In the 1950s and 1960s, international development actors posited that there was a linear progression from hunter-gatherers through to "highly developed," "modern"

industrialized nation-states made up of productive workers (and intelligent, controlled reproducers) that progressed and developed individually. The nation-state developed through the cumulative effects of these individual activities. This conceptualization of modernity and development relied heavily on models of linear progress and growth stages, often drawn from the natural sciences. The model of the rational, developing whose individual actions create a greater good drew from Enlightenment ideas and classical economic theorists such as Adam Smith. Although there was important work done during this period concerning social, political, psychological, and other forms of development (see Adams, 1977 for a review), the general focus of the field came to rest solidly on economic development as, depending on the author, either the absolute or the proxy for all other forms of human and state development.

This early work laid the foundation for current mainstream conceptualizations of international development. It argued that all states could achieve development if they followed the path already trod upon by Western states—modernization through industrialization, urbanization, and population control. Within this framework, education came to play a major role in state development models, as education was the primary means to increase individual productivity. It should also be noted that development education models, which had missionary roots in most poor states, were also seen as central to “civilizing” non-white, non-Christian people.

The curricula of western schools inculcated a distaste for agrarian (and manual) labor and fueled students’ desire to move to urban, “modern” spaces (Corby, 1981). Schooling thus forwarded economic and sociocultural practices viewed as central to development and modernization. Funding for international development education reached its highest levels until the 2000s during the 1950s and 1960s, receiving up to 6–7% of all international development funding.

The burgeoning field of development economics laid out what remains the primary rationale for development education: because state development occurs through the aggregation of increased productivity on the part of its constituent members, the best way to develop the state is to increase constituent members’ human capital, and thus productivity. In these models, education is purely functionalist, and education is a worthwhile investment only to the extent that it translates into increased worker productivity (and later into other easily quantified health, civic participation, and lifestyle outcomes such as decreased fertility). Productivity was initially measured in terms of worker wages in the formal labor sector, and so growth of the education sector only remained productive as long as the labor market could absorb graduates. Over time, increased productivity was measured in more diverse ways, such as by increased agricultural output.

This emphasis resulted in the 1950s and 1960s in a strong focus in international development education on secondary and particularly tertiary education (Buchert, 1995), where the professionals needed for development and modernization (doctors, economists, planners) were trained, as well as on planning for the “modern” labor market. Bilateral organizations (such as GTZ and USAID), multilateral organizations (such as UNESCO), and Foundations (such as Rockefeller and Carnegie) all played significant roles in first sending people from poor and newly independent states for training in Europe and in the United States, and later building secondary and tertiary education institutions in poor and newly independent states.

In the newly independent states, the development education focus was also often adopted by independence leaders, who emphasized the need for their country to staff their own bureaucracies and professional institutions in order to be truly liberated. Nonetheless, development education models focused on tertiary and secondary education sidelined the common pre-independence-era focus on addressing the inequities of colonization through the massification of (early) educational opportunities. For example, following independence in 1964 in Malawi, the new government bypassed pre-independence promises of education for all and spent the majority of the education budget building the University of Malawi, the first tertiary institution in the new state. It received international development support for this effort. In socialist states like Tanzania, the focus of education development remained on mass primary education. Schooling was still conceptualized as human productivity development, but it was the state's, not the market's, responsibility to harness and plan for the use of this improved capacity.

The critiques of this approach diversified over the decades. Early critiques included those that focused on conceptual flaws in the economic models being used to argue for the "productivity" of education, such as Balogh's (1964) scathing set-down of the economic models used to measure the effects of education; those that addressed fallacies in the concept of linear progress and development; those that argued that educational experiences were not all equal and models were needed to address the "black box" of classroom practices and education processes; and those that expressed concerns that development education practices were fostering neo-colonial relations.

By the late 1960s and early 1970s, critics were discussing the failure of development education investment to lead to predicted economic growth in many poor states; were increasingly questioning the nature of the relationships between so-called development donors and recipients (Altbach, 1971); and drew on Marxist and dependency theories to argue that one of the reasons for the "failure" of education to increase equity and life chances was that the model of education promulgated by development education experts was not a functionalist black box, but instead a system designed to reproduce class (and other) inequalities (Carnoy, 1977).

1970s

By the 1970s, there was a countermovement amongst many of the states that were targets of international development funding. They argued for a focus on basic needs as opposed to elite services and fought to center discussions of global and state inequality in international development debates. There were new discussions about the role of schooling in fostering neocolonial, as opposed to liberatory, relations (Keith, 1978). And dependency theory provided a new framework through which to make sense of relations among "developed" and "developing" states and to understand the failure of development loans and grants to achieve their expected results (Carnoy, 1977; Altbach & Kelly, 1978; Lewin & Little, 1984; Little, 2000).

In the education arena, a rich discussion developed about how to improve the relevance of formal education systems in poor people's lives, as did interesting work on and critiques of non-formal and adult education as alternatives to formal education models (Sheffield, 1972). There were new demands for international support for basic

education for all (now discussed as a basic need), paralleled by a body of economic studies that purported to find improved state returns on investments in primary, as opposed to secondary or tertiary, education. At the same time, critics were pointing out that economic models used to understand the effects of development and education were not able to “count” its effects on women or their work (Kelly & Elliott, 1982), agricultural work, or indeed the informal economy.

At the same time, educational investment by states and international development organisations generally still targeted secondary or higher education, and development resources for education began to fall as a growing pessimism concerning the inability of the past decades’ educational expansion to improve economic growth grew (Weiler, 1978). This trend of disinvestment in and growing cynicism about formal education expanded when the oil crisis hit. As “developed” economies wobbled, international debts were called in and resources for new loans slowed, causing crises in newly independent and poorer states with high debt loads (Frieden, 1992). This crisis effectively silenced the development target states’ countermovement.

1980s

In the 1980s, Structural Adjustment Policies or Programs (SAPs) circled the world and transformed the funding available for and conceptualization of the role of education in international development. Aimed at restructuring the macroeconomic policies of states in crisis, SAPs were promulgated and enforced by the IMF and the World Bank. They included reforms such as state privatization of national resources, floating national currencies, removing state subsidies for agricultural and food goods, removing trade barriers, and shrinking the state. SAPs were based on the neoliberal notion, increasingly popular in Europe and the United States, that the market was always more efficient than the state (Carnoy, 1995; Arnove et al., 1996; Torres, 2002).

Particularly in early SAPs, social services like education were reconceptualized as peripheral-to-state responsibilities, and in fact likely to be ineffective and unproductive to the extent that they were state-provided. Education, health, and other social services were defunded and privatized, often at least in part to pay “donor” states back as older development loans came due (Reimers & Tiburcio, 1993). For example, Malawi implemented a SAP in 1981. Funding for education dropped from 13.7% to 8.9% of government expenditures. At the same time, debt servicing increased from 17% to 36% between 1977 and 1986 (Kaluwa, 1992). Such declines in overall educational expenditures were often accompanied by international restrictions on civil servants’ salaries and hiring, which weakened the long-term capacity of SAP-ed government institutions to provide services and train the next generation of administrative leaders.

Throughout this period, mainstream international development education discourse focused on the need for states to increase the efficiency of education systems so that governments could reap greater benefits with fewer resources (Fuller & Habte, 1992). The World Bank led a movement to introduce cost sharing in education, a policy perspective that argued for the need to have individuals and their families pay a greater proportion of the costs of schooling—even primary schooling (Tan et al., 1984); and reframed repetition and dropout as systemic inefficiency issues. There were also early discussions about the appropriate role for the private sector in education provision (Colclough, 1991).

There were significant critiques levelled against SAP-influenced education approaches, ranging from protests over the absolute cut in funding and services for poor people; to critiques of neoliberalism and its recalibration of state-market-society relations; to feminist critiques of patriarchal development models and practices (Beneria & Sen, 1981); to critiques from anthropologists and postmodernists about the assumptions of Western, progressive concepts embedded in most development education models (Masemann, 1982); to growing concerns about the lack of widespread participation in development decision-making. New arguments in support of basic education, both from progressives interested in increased equity and economists who claimed evidence of the supremacy of primary education investment returns in poor countries (Psacharopoulos, 1987), gained momentum.

1990s

In 1990, the World Conference on Education for All (WCEFA) was held, heralding a new discursive phase in international development education. The WCEFA was the culmination of years of economic and human rights arguments put forward by international organizations (multilateral and non-governmental in particular) and poor states to address rising global and national inequity and their desire to have individuals and states manage their own development. The conference focused on basic education as a fundamental human right and on the state as the body responsible for its provision. It centered economic models of educational utility and effects that argued that primary education, particularly for girls, was one of the best investments a state could make in economic growth (Lockheed & Verspoor, 1991). It resulted in a strong international development education focus on expanding access to primary schooling, some would argue at the expense of educational quality.

Based on the WCEFA and the mounting evidence that SAPs were fuelling the abjection of millions of poor people without resulting in improved economic growth, international development organizations heralded a new idea: structural adjustment “with a human face”. They began the arduous process of refunding support for the social service sectors they had so recently helped to dismantle. Resources for social services increased a bit, resources for education became more focused on primary education, and calls for user fees in primary education were discarded; however, there was no net increase to education funding (Bennell & Furlong, 1997). A programmatic and policy focus on educational expenditure and system efficiency continued, though discussions about the relevance and efficiency of primary education faded somewhat in the face of human rights arguments that all children had the right to a basic education and could learn to be literate and numerate—the two tasks repositioned as the primary goals of basic education.

The WCEFA was the first global education conference to include NGOs in any significant way (Mundy & Murphy, 2001); their inclusion reflected growing critiques of development education practices as neo-colonial, and a new willingness on the part of state and international governmental organizations to recognize the potential contributions of “civil society” organizations and participatory approaches in improving development education practices and outcomes. This was also the gender decade in international development education; based on global data showing significant gender gaps in enrolment rates in many areas of the world (Hill & King, 1995), organizations such as USAID

provided significant resources to support multifaceted initiatives designed to improve the status of girls' education. For example, in Malawi, USAID funded the Girls' Attainment in Basic Literacy and Education (GABLE) project, which included support for national policy reform, the creation of a gender-appropriate curriculum unit, gender-sensitive teacher training, a social mobilization campaign designed to increase community support for girls' education, and a girls' scholarship program for non-repeating female students.

During this decade, there was also increasing interest in sector-wide funding approaches (Harrold, 1995). Development experts argued that traditional project-based support produced short-term, unsustainable, uncoordinated efforts with parallel administrative structures to official government education structures. Sector-wide approaches, in which international organizations pledged support for a national budget in exchange for government agreement to meet certain conditions, seemed a mechanism through which to address many of these critiques (Ratcliffe & Macrae, 1999). Extensive aid accountability frameworks were also put in place to address concerns about efficiency of aid use in various countries. These measures almost always targeted aid recipients, not providers, despite evidence that there was corruption and administrative incompetence on both sides (Therkildsen, 2001).

2000s

By the 1990s, it was clear that the "bitter pill" of market (neo)liberalization had not resulted in the economic growth or improved quality of life assured to citizens in many poor states. In fact, as measured by life expectancy, educational completion, GDP/capita, and many other development measures, the last 25 years has resulted in an absolute decline in the standards of living of many people in the African region (Ferguson, 1999; Arrighi, 2002). Recently, the World Bank and IMF have acknowledged (even as they continue to push similar reforms) that SAPs have failed (SAPRIN, 2004). In the wake of these acknowledgments, international arguments against state provision of social services have shifted in important ways. Poverty alleviation plans and programs that include some attention to public provision of basic social services have been encrusted over earlier forms of neoliberal state transformation. There are now even some calls from European states that supported SAPs for poor states to "take responsibility" for basic social services like education.

This shift has resulted in an increase in total international development spending on education, raising levels back up to those seen in the heyday of the 1950s and 1960s. Not only international resources to education have increased; in the wake of the WCEFA, a number of countries (e.g., Malawi, Uganda, Kenya) implemented EFA-style fee-free primary education systems (usually as part of an officially democratizing political process (Kendall, 2007)) and now spend upwards of one-quarter of their entire annual budget on education. There has been rapid growth in NGO involvement in development education activities in many poor states, and they have become increasingly networked (Mundy & Murphy, 2001). Communities are also investing significant (and in some cases, more) resources in their children's education, partially in response to their perception that education offers their children the best chance of mobility in a globalizing environment.

These funding increases mirror increased belief in and demands on formal education; as a number of authors have noted, education is once again viewed as a development panacea (Vavrus, 2003), and formal education is expected to do everything from grow economies, to prevent new HIV infections, to create small and healthy families, to socialize democratically-oriented citizens. Although as in all social service areas there is increasing pressure to conceptualize the education sector as a market and educational services as a tradable good, education has emerged as the social service in which the state has the most viable, internationally supportable, and public role to play. This is due in part to the history of state educational provision in the United States and Europe, to historical models of schooling as a (re)producer of nation-state citizens, and to the continued conceptualization of basic education as direct human capital development.

As the actors and resources in the development education arena have increased and diversified, as the political reality of primary-school leavers clamoring for secondary school places has hit, and as investment in primary education has proven to be less transformational than expected, there are now calls for a more “balanced” approach to education funding. Sectorally, this has translated into support for improved primary educational quality, improved secondary and tertiary education access, and growing discursive support for early childhood and adult education. In terms of implementing agents, national governments’ position as the central development partner continues to be undermined by the predominant neoliberal rationality in international development. NGOs continue to be viewed by many international governmental organizations as more representative and more efficient development partners than central governments, and a growing percentage of international development funding is being channeled through NGOs instead of states (Hearn, 1998; Makoba, 2002). Likewise, and following the roll-out of decentralization reforms often “inspired” by international organizations, central governments and NGOs are facing new competition for funds from local government bodies.

Participatory approaches, called for by 1980s and 1990s critics of development practices, are now, at least discursively, fully integrated in most development planning practices (World Bank, 1996). For some critics, this is seen as a co-opting of radical critique, for others an honest effort by development organizations to improve their practices (Kendall, forthcoming). More broadly, international development education has been folded into both global plans for development transformation (such as the Millennium Development Goals) and into the poverty alleviation frameworks that now shape most bilateral and multilateral organizations’ funding for new development activities. In both cases, education is usually incorporated in two ways: as a call for primary schooling for all, and as a call for gender equity in formal education, and thus development, opportunities (Mundy, 2006). The poverty alleviation approach, coupled with sector-wide funding approaches and joint budget financing (Walliser, 2002), has led to a narrowing and intensification of development resources and targets in a smaller number of states throughout the world.

New actors, such as family foundations, individual donors, local governments, private organizations, community-based organizations, and universities have received increasing attention in the development education arena, as have new issues including HIV/AIDS, early childhood education, educational quality, and child-centered

pedagogical approaches (Tabulawa, 2003). Perhaps the most important new focus is on improving within-classroom resources and practices—that is, affecting change in the traditional educational “black box.” In most of these efforts, student learning (usually as measured on standardized tests) is the ultimate measure of educational success. For example, a current USAID education project, the Malawi Teacher’s Training Activity (MTTA) provides preservice and in-service training and support to the education sector in the areas of English, science, math, and life skills, as well as in gender equity in the classroom. It does so by providing preservice teacher training materials, training school personnel to use local resources to create their own in-service trainings and teaching/learning materials, providing books from international sources to Teacher Development Centres so that teachers can update their content knowledge, and creating a mobile teacher training troupe that provides support for improved teaching and learning through the exchange of innovative practices and ideas across school zones. Effects are measured primarily by students’ and teachers’ increased content knowledge scores on standardized exams.

Discussion

Interest in globalization, and particularly the role of education in the creation and distribution of information, opportunity, state and worker competitiveness, and individual characteristics such as flexibility, has led to a renaissance in international development education (Crossley, 2000). This same movement is destabilizing concepts that have underpinned the field for over 50 years. Perhaps the most important of these is the continued emphasis on the individual and the nation-state as the central units of analysis and action in international development education. Given the practical effects of globalization on the economic, political, and social coherence of states and people’s everyday lives, this seems short-sighted. Discussions about the appropriate roles of NGOs, private entities, substate and regional actors and institutions, and local and/versus international labor markets point to the variety of daily educational and life experiences that are no longer primarily organized by or within the state, and the extent to which the traditional concerns of development—progress, life improvement, equity—are no longer (if they ever were) concerns that make sense to discuss within the confines of state borders. A growing literature on globalization and education (Carnoy & Rhoten, 2005; Welmond, 2005; Suarez-Orozco & Qin-Hilliard, 2004; Burbules & Torres, 2000; Stromquist & Monkman, 2000; King & Buchert, 1999) highlights the extent to which the decisions involved in education practices are (differentially) global in nature, and a parallel literature on global imaginaries (Ferguson, 2002) points to the transformation of people’s understandings of belonging and opportunity, which have been poorly addressed by development education researchers and programs.

These changes threaten to destabilize the economic and human rights rationales that have dominated development education since its inception, and this may be a good thing. For what continues to be lacking from many of the critiques of development broadly, and development education particularly, is real and sustained engagement with the question of what, exactly, education for development might look like

and mean in people's lives. It is clear that such a discussion can no longer emanate from and respond to the demands of any one state or region, as it has historically done to Western Europe and the United States. It is equally clear that there will be no single imaginary, and that the currently taken-for-granted models and goals of education and its relation to state, market, society, and international relations of power, authority, and survival are in flux. Funding for development education is on the rise, and there are reasons to believe that these funds can positively affect (by both "international" and community measures) the lives of people, and even some poor people, in poor states. The MTTA project described above, for instance, has had significant effects on the classroom experiences and educational outcomes of teachers and students in some target schools, and it has positively transformed relations of power and authority among students, teachers, parents, and district officials in such a manner as to both expand teachers' willingness to learn from multiple sources (including each other and students), and to improve community support of teachers and schools. These shifts have in turn resulted in classrooms that provide students very different, and potentially empowering, messages about learning, authority, knowledge, and success. For example, they provide students with opportunities to assume academic leadership roles within the classroom and to see teachers work collaboratively with other teachers and with community members around knowledge production.

Such positive outcomes appear to occur most frequently when the "recipients" of aid take part in development education practices at all stages of the development programming process (planning, implementing, monitoring, and evaluating), and particularly when they play a role in determining the intended outcomes of the activities. Positive outcomes are also more likely in situations where initiatives are given time to develop and to improve, and enough funding to continue for a long enough period of time to become institutionalized. This rarely occurs in the international development arena, which usually runs on 3–5 year funding and idea cycles.

There is also reason for caution in supporting international development education efforts. First, even by development standards, there are plenty of failed development education projects and plans. As with all development arenas, these failures may outnumber the successes and may have actually negatively impacted the lives of those they targeted, both directly (as in sending more children into unhealthy educational environments) and indirectly (through, for example, increased state dependence on international monies to fund educational promises and increased domestic spending on debt repayment). Even development education successes may be shallow. For example, a report on USAID support for education in Malawi notes that projects that achieved their official goals (e.g., improved teacher training) were hampered from having broader effects by the absence of many students attending class on a regular basis, of classrooms, and of basic teaching materials (Anzar et al., 2004).

Second, there are serious questions about whether education is the key human right or economic investment to transform the lives of poor people. When poor states spend one-quarter of their budget on education without significant changes in their citizen's life experiences, we need to question the assumptions that underlie international support for further investment in education.

Third, western education occurs to individuals, and in current models, it is individuals who succeed (or more commonly fail) to progress as a result of their formal schooling experience. It may thus serve, as Marxists theorists argued in the 1970s, as a system to constrain people, not as a liberatory process. And development education resources do not address global inequities, they reinscribe individuals and the state as the units of analysis that succeed or fail to progress.

Many of the concerns of people living in less affluent countries—how to cobble together a survival; how to stay healthy and care for the ill; how to access increasingly privatized resources such as water and land; how to transmit moral, cultural, and religious practices to the next generation—are simply not on the international development education radar.

People in less affluent countries are responding to this reality in perfectly reasonable ways. For a minority, education is absolutely central to geographic mobility, which in turn is central to individual and familial survival. For them, continued educational investment makes sense. For many others, though, schooling is a brief blip that may or may not provide skills and lessons useful for daily survival and thriving (Kendall, 2007). In countries where neither formal labor, nor expanded agricultural opportunities, nor opportunities to travel to more affluent countries are growing, schooling may seem relatively disconnected from daily needs or future opportunities. Not surprisingly, enrolment rates are decreasing in some of the poorest countries in the world, and in others, dropouts are accelerating.

The international development community is always looking for the next panacea: sustainable environment? Global health? The extent of future support for educational resourcing from communities, states, and international actors will depend on the field's capacity to create space for a multiplicity of actors and institutions to reimagine the global relations among education, equity, and individual and communal survival and flourishing. At a minimum, this will require extensive engagement with ideas that move beyond the current universalizing neoclassical economic orthodoxy (Harriss, 2001) and human rights frameworks to address the diverse realities of people's changing lives, survival strategies and dreams. From these may be drawn, the shape and scope of potentially empowering educational practices that might be supported by international development education practices.

THE OECD AND GLOBAL SHIFTS IN EDUCATION POLICY

Fazal Rizvi and Bob Lingard

Introduction

In 1994, the Organization for Economic Cooperation and Development (OECD) published an important account of its work on education. The author of this account was none other than George Papadopoulos, the highly regarded deputy director responsible for education in the then Directorate for Social Affairs. Although celebratory in tone, Papadopoulos closely examined the planning and implementation of the organization's educational activities between 1960 and 1990, situating them within the context of the OECD's broader interest in economic policies. He suggested that this period was characterized by much debate and various shifts in policy focus. In the 1960s, for example, quality in education and human resource development were the major issues, replaced in the 1970s with concerns of equality of educational opportunity and the democratization of education (Papadopoulos, 1994: 202).

At the end of 1980s, however, Papadopoulos sensed further changes occurring within the OECD, with educational policy again becoming more closely aligned to economic imperatives. He noted that: the exponential growth of knowledge and rapid technological change; economic restructuring and changes in labor markets; changing attitudes to the role of the state in initiating and funding public policy; the emergence of new concerns about social equity and cohesion; and a market-driven and consumption-oriented society and the growing political, economic, and cultural interdependence of countries inevitably demanded some shifts in the OECD's policy work in education.

Little did Papadopoulos realize in 1994, however, how extensive and profound these shifts were likely to become, both in relation to reshaping the context within which the OECD works and to the ways in which the OECD would interpret and respond to this context. The issue of "globalization," for example, does not feature in Papadopoulos' analysis; and "a new humanism" he regards as an integral part of contemporary culture does not even appear on the organization's current agenda. Although the concepts that were central to the OECD's educational work during 1960–1990, such as educational equality and social cohesion, have not been abandoned, they have been thoroughly rearticulated, given new meaning, becoming instruments of economic policy associated with a new vocabulary of the knowledge economy. And although the OECD remains concerned with issues of educational reform, accountability and social

efficiency, it no longer treats them as matters of philosophical debate, but as issues to which it can apply its growing technical expertise.

Significantly, also, the OECD's work has now become embedded within a new multilateral system constituted by various international policy networks, involving not only its member countries but others as well.

In this chapter, we seek to do two things: to understand how the contemporary processes of globalization have affected the OECD's policy work in education, how, in turn, the OECD has ideologically named these processes, and has sought to steer its members and non-members alike towards its preferred conception of education, through both a new ideological vocabulary of reform, which, following Taylor (2004) we refer to as a "social imaginary," and its growing technical expertise in monitoring educational performance.

A Historical Background

Established in 1961 out of the Organization for European Economic Cooperation (OEEC) funded under the Marshall Plan for the economic reconstruction of Europe, the OECD has variously and simultaneously been described as a think tank, a geographic entity, an organizational structure, a policy-making forum, a network of policy-makers, researchers and consultants, and a sphere of influence (Henry et al., 2001: 1). In formal terms, the OECD views itself as an intergovernmental organization of some 30 of the world's most developed countries, which produce two thirds of the world's goods and services, and which are committed to the principles of a market economy and a pluralistic democracy (OECD, 1997). Article 1 of the OECD's convention requires its members to promote policies designed to develop the world economy and trade on a multilateral and nondiscriminatory basis.

Although primarily an economic organization, the OECD has, since its inception, emphasized the role education must play in both economic and social development. Within the organization however, there has been much debate about the ways in which economic and educational policies might be related. In the 1970s and 1980s in particular, the European countries sought to "tone down" the dominant US versions of market liberalism, with their own distinctive social-democratic agendas, refusing to view education and social policies as secondary to, or instruments of, economic policies. Haas (1990: 159) has suggested that the OECD could best be viewed as "a rather incoherent compromise between the United States and the European members," especially with respect to the role education plays in the total polity.

Indeed, as Papadopoulos (1994: 11) points out, in the OECD's original charter there was no independent structural location for education, though there was always an "inferred role," derived from early human capital formulations of links between economic productivity and educational investment, then conceived somewhat narrowly in terms of boosting scientific and technological personnel capacity and, by extension, of improved and expanded science and mathematics education in schools. Hence, education-related activities were initially carried out under the rubric of the Office for Scientific and Technical Personnel, which in turn grew out of the former OEEC's pivotal work in mapping the technological gap between

Europe and North America, against the backdrop of the geopolitical issues relating to the Cold War.

It was not until 1968 that the Centre for Research and Innovation (CERI) was established within the OECD, partly as a result of a growing recognition within the organization of the “qualitative” aspects of economic growth – “as an instrument for creating better conditions of life” – and, along with that, a more comprehensive view of education’s multiple purposes. By 1970, the organization recognized a fuller range of objectives of education – a less “economistic” view of education policy, as Papadopoulos (1994: 122) puts it, enabling it to attach equal importance to education’s social and cultural purposes. For most of the 1970s and 1980s then the dominance of economic concerns within the OECD was tempered by the recognition of the social dimensions and purposes of economic growth and development.

This was clearly evident in the educational work the OECD pursued, organized under four programs: two of them emerging from the Education Committee and CERI’s Governing Board, with the other two being the more specialist Programmes of Educational Buildings (PEB) and Institutional Management in Higher Education (IMHE). An illustrative list of the projects sponsored by the organization during the 1970s and 1980s includes analyses of: school pedagogy and curriculum, educational disadvantage, multicultural education, education of girls, linguistic diversity, alternative education, early childhood education, links between school and work, school–community relations, youth employment, youth at risk, people with disabilities, teacher education, educational and performance indicators, the economics of education, educational technology, recurrent education and lifelong learning, and adult literacy.

These themes were largely supportive of national agendas, brought to the OECD by the member countries. They pointed to the OECD’s consensual approach to decision-making in which nation-states retained a great deal of autonomy in defining the ways they wished to use the resources of the organization, in both thematic and national reviews. These reviews indicated the OECD to be a broad ideological church respectful of the diversity of ideological positions. According to Papadopoulos (1994), to view OECD as a homogeneous unit with a narrow, static agenda is to fail to capture its educational reach, the contestations within its various forums and the ideological layers that underpin its charter aimed at both economic and social development.

This is not to deny the existence of deep ideological tensions within the OECD. Any analysis of the debates until the mid-1990s both within the organization’s committees and its secretariat reveals an ideological cleavage between social-democratic and neoliberal policy stances. These tensions however were resolved in the way the OECD worked: without any prescriptive mandate it operated through processes that involved its “traditions of transparency: of providing explanations and justifications for policy, and of engaging in critical self-appraisal” (OECD 1998). As Martens et al. (2004: 15) point out, the OECD does not have any legally binding mandate over its members; nor does it have the financial resources at its disposal to encourage policy adoption. It thus seeks to exert influence through the processes of “mutual examination by governments, multilateral surveillance and peer pressure to conform or reform.”

Recent Transformations

Papadopoulos provides a convincing historical account of how, until the early 1990s, the OECD's educational work can usefully be characterized as involving a struggle between its concerns for promoting economic efficiency and growth, on the one hand, and education's broader social purposes, on the other. Since the mid-1990s, however, this tension, we want to argue, is no longer so evident, as education is once again increasingly viewed in instrumental terms, as a handmaiden to the organization's primary interest in economic matters. With a greater focus on the changed context in which education now works and armed with a new discourse of globalization and the knowledge economy, the economic efficiency perspective now dominates the OECD's educational work, which is increasingly more technical and data-driven, and which has replaced the earlier normative debates about the multiple purposes of education.

Equally, the way the OECD works and the manner in which it relates to its members have changed. Indeed, this much is explicitly acknowledged by the organization in suggesting that:

OECD has evolved greatly in the globalising world economy. It has been 'globalising' itself, notably through new Members and dialogue activities. . . . Further, analysing the many facets of the process of globalization, and their policy implications, has become the central theme in OECD's work, as the challenges and opportunities of globalization have become a high priority of policy-makers in OECD countries. (OECD, 1996a: 15)

The OECD now asserts – perhaps accurately – that “a broad consensus exists on many aspects of the policy requirement for a globalizing world economy.” In this way, the OECD has made considerable use of the idea of globalization in both redefining its policy program and in reconceptualizing its relationship to member countries, often prescribing the manner in which they should interpret and respond to the pressures of globalization, and take the opportunities offered by the global economy.

However, in articulating the logic of globalization in this manner, the OECD appears to “reify” the economic relations it regards as “globalizing,” treating them as if they were self-evident and inevitable. This has the effect of masking some of the normative assumptions underlying its conception of globalization, treating them as if they were beyond political debate. Yet, globalization is a highly contested term that refers to a whole range of social processes. Indeed, it is possible to interpret globalization in a number of contrasting ways (Held & McGrew, 2005). The OECD's perspective on “globalization” seems to accord market relations conceptual primacy, referring to a set of social processes that imply inexorable integration of markets, nation-states, and technologies. It correctly associates globalization with technological revolutions in transport, communication, and data processing, but explores only their economic implications, and not the cultural transformations to which they have also given rise.

And in so far as the OECD considers the political aspects of the global economy, characterized as informational, networked, knowledge-based, postindustrial, and service-oriented, it suggests a radically revised view of the roles and responsibilities

of the state (OECD, 1995). It assumes that the old centralized bureaucratic state structures were too slow and sclerotic and “out of sync” with the emergent needs of transnational capital. It therefore calls for a minimalist state, with a greater reliance on the market. It argues for new devolved forms of governance that are more compatible with the so-called demands of the global economy. It recognizes increasing levels of cultural interactions across national and ethnic communities, but views this as both an opportunity and a challenge to the social cohesion necessary for economic growth and development.

A problem with this account is that it views globalization in terms of an objective inexorable set of social processes. This focus on description however overlooks the fact that globalization is also a subjective phenomena, which involves actual human agents interpreting the conditions of interconnectivity. Nor does it permit the possibility that it may be a deliberate, ideological project of economic liberalization that directs people towards more intense market forces (see Bourdieu, 2003); and that it is based on a politics of meaning that seeks to steer them towards a certain taken-for-grantedness about the ways in which the global economy operates and the manner in which culture, crises, resources, and power formations are filtered through its universal logic. It thus “ontologizes” the processes it describes, seeking to create subjects who view policy options through the conceptual prism of an assumed logic. As Schrato and Webb (2003: 1) point out, represented in these terms, “globalization” designates certain power relations, practices, and technologies, playing a “hegemonic role in organizing and decoding the meaning of the world.”

Given this representation, the OECD no longer seems to entertain broader philosophical debates about the purposes of education, but locates them instead within its presumed normative commitment to globalization’s ideological forms, articulated in terms of a neoliberal logic of markets. This depoliticization of educational issues leads the organization to reconceptualize its policy work in mostly technical terms, concerned with questions of how best to understand the so-called imperatives of globalization; how education can be a more efficient instrument of economic development; how greater accountability of educational systems can be ensured; and how education should develop social subjects who view the world as an interconnected space in which informational networks play a crucial role in sustaining market activity.

Indeed, within this neoliberal economic logic, the OECD now accords greater importance to education than ever before. So much so that in 2002, it established a separate Directorate for Education, something it had resisted for most of its history (Papadopoulos, 1994). In establishing the Directorate, the secretary-general of the OECD (2004) stressed that “Education is a priority for OECD Member countries and the OECD is playing an increasingly important role in this field. Society’s most important investment is in the education of its people.” This observation is clearly based on the OECD’s interpretation of the requirements of the global economy, in which knowledge is assumed to be a key ingredient and in which innovation and commercialization of knowledge are considered major drivers of economic development.

Given these normative convictions, it is not surprising then that much of educational policy deliberations at the OECD are concerned with technical issues, as is evident in its work program for 2005–2006, which suggests that internationally comparable

statistics and indicators must underpin much of the educational work of the OECD, and that the ultimate outputs of its policy recommendations must be designed to increase both the quality and equity of education systems. Listed as major concerns are issues of equity in access and outcomes, quality, choice, public and private financing, and individual and social returns to investment in learning. Underpinning this list is the conviction that education is a major factor in contributing to human capital formation and economic growth, and that policy research in education should therefore be directed to this end.

Changing Modes of Working

With this conviction firmly in place, the OECD's mode of working has undergone substantial shifts. According to Papadopolous (1994: 14), the OECD's general approach to education between 1960 and 1990 was based on international cooperation, which involved its education committee to identify problems on which such cooperation was felt to be useful. Country educational policy reviews were conducted on a voluntary basis, and followed "a *sui generis*' pattern in terms of their methods of investigation, coverage and periodicity." The Secretariat in turn brought to the education committee newly emerging policy concerns, around which it was authorized to conduct thematic reviews. And although these reviews made recommendations, there was no mechanism for ensuring that they were implemented, beyond encouragement and advice.

In more recent years, however, while the OECD has retained this general rhetoric of international cooperation, the balance between the political work of the education committee and the technical tasks performed by the secretariat has shifted. With a greater agreement over the organization's ideological position, the debates within the committee are no longer as intense, and are replaced by the setting of work priorities and a consideration of the administrative issues of coordination and monitoring. The OECD now devotes more resources to the collection of comparative performance data in education than it has ever done before. Equally, the country reports no longer occupy the centre stage; and it is around the performance data that the organization explores issues of educational equity and outcomes. The notions of multilateral surveillance and peer pressure have always existed within the OECD, as we have already noted, but in the current context, the organization insists that the effectiveness of policies requires mutual adaptation and that the "peer pressure" system is essential for countries to become more transparent, to accept explanations and justification, and to become self-critical (OECD, 1998: 2).

The OECD has traditionally viewed itself as a unique forum, which enables its members to examine and formulate their distinctive policies in both economic and social spheres. However, in recent years, its outreach and impact have become greatly extended, through its work with 'non-member economies' and through the global recognition of the technical expertise it has acquired in comparative performance assessment. Its Directorate for Education, for example, has developed a Unit for Cooperation with Non-member Economies (NME), the terminology used by the OECD to refer to non-member countries. The Directorate's interest in NMEs is based on the view that in the context of

a global integration of economic activity, it is no longer possible to understand the economic competitiveness of its own members without focusing also on comparative issues, and monitoring the challenges posed to them by transitional economies, especially those that are now achieving higher levels of growth.

Of particular interest to the OECD then are the transitional and fast developing economies of China and India. Its Global Relations program is based on its realization that in a globally integrated economy, an understanding of and strategic cooperation with these economies is vital for the sustainability of the economies of its own members. It therefore conducts a wide range of policy dialogue and capacity building activities not only with China and India but also with other NMEs. Through its *Country Programmes, Regional Approaches and Global Forums* and the like, it shares best policy practices with them on matters that bear on OECD's policy debate. It holds regular global forums on such policy themes as the knowledge economy, governance, international investment, competition, agriculture and education, but on an assumption that 'the OECD has progressively evolved from the traditional concept of 'outreach' in its relations with the rest of the world to a two-way flow where giving access to and participation in core OECD work and processes is as important as disseminating OECD's best practices' (OECD, 2007: 4). Ultimately, the OECD insists that its global relations program is based on its desire to contribute to the harmonious functioning of the global economy, to promote shared prosperity and to encourage shared knowledge for better public policy.

The OECD's perspective on globalization has also led it to develop formal links with a number of other international organizations, with the expressed purpose of helping bring the OECD's institutional and policy expertise and technical know how to NMEs. It has therefore worked, for example, with the World Bank and UNESCO on the development of a World Education Indicators (WEI) project. WEI is a joint initiative of these organizations designed to provide a set of comparative educational data about transitional economies. The OECD's role in the project has been to provide technical advice based on its long history of work with performance indicators. But as Rutkowski (2007) points out, this role is grounded in the OECD's neoliberal precepts, and it is difficult to separate the OECD's technical expertise from its normative assumptions about the role education must play in the development of the global economy.

These normative assumptions now constitute a global ideology that both informs the OECD's policy work in education and have become central to its multilateral relations with NMEs and international organizations alike. This has of course happened within a broader context of the changes in the ways in which nation-states now relate to and work with each other. The traditional conception of the nation-state as a fundamental unit of world order, a unitary phenomenon characterized by its relative homogeneity with a set of singular purposes, has been replaced by a fragmented policy arena, permeated by transnational networks as well as domestic agencies and forces. As Held & McGrew (2005: 11) argue, 'the contemporary era has witnessed layers of governance spreading within and across political boundaries', transforming state sovereignty into a shared exercise of power. With the emergence of new patterns of political interconnectedness, 'the scope of policy choices available to individual governments and the effectiveness of many traditional policy instruments tends to decline' (p. 13).

However, this multilateral cooperation does not occur in a politically neutral space, but in a space that is characterized by asymmetrical relations of power. The flows of information and policy ideas are skewed towards the most powerful countries and their political interests. However, as facilitators of information flows and policy dialogue, international organizations have acquired greater power and influence than ever before. In the past the OECD viewed itself a forum for open dialogue with its members, but it is now clear that it has increasingly become a policy actor in its own right (Henry et al., 2001). Both through the construction of its agenda for policy dialogue and its technical statistical work, it displays a marked preference for certain policy priorities. This preference is now carried over into its multilateral work. This much is evident in the ways in which the OECD has promoted a new social imaginary around the discourse of the knowledge economy.

A Social Imaginary of the Knowledge Economy

In recent years, scholars such as Taylor (2004) and Appadurai (2000) have used the notion of ‘social imaginary’ to show how ideologies are promoted through social imaginaries, in ways that make them appear self-evident and natural. A ‘social imaginary’ (Taylor, 2004) represents a discourse, or a set of overlapping discourses, that is at once descriptive and prescriptive of conceptions of how practice is best organized around policy, is directed towards certain outcomes and is organized around a set of norms. For Taylor, the idea of social imaginary involves a complex, unstructured and contingent mix of the empirical and the affective – not a ‘fully articulated understanding of our whole situation within which particular features of our world become evident’ (Taylor, 2004: 21).

Importantly however a social imaginary is not simply inherited and already determined for us, it is rather something that is in a constant state of flux. It is through the collective sense of imagination that discourses and institutional practices are created, and are given coherence, and acquire the character of a taken-for-granted commonsense. Appadurai (1996) has analysed the role of social imaginary in the formation of subjectivities within the globalizing context in which we now live, a context that is characterized by diffusion of social images, ideas and ideologies across communities around the world. This diffusion is facilitated by electronic media, mass migration and the mobility of capital and labour.

Within such a context, international organizations play an important role, in directing people away from the dominant national narratives to shared transnational imaginaries, through the global distribution of particular policy ideas and ideologies that link ‘states together and transformed sovereignty into the shared exercise of power’ (Held & McGrew, 2005: 11). In this way, as Bourdieu (2003) has pointed out, there is a slide from the descriptive usage of globalization to a normative or performative one that elides the politics of meaning surrounding concepts such as the ‘knowledge economy’. As Kenway et al. (2006: 4) point out, “the contemporary policy discourse of knowledge economy, with its interlaced ideas about knowledge, information, learning, economy, and society, has become so influential that it has assumed the status of truth, dominating policy lexicon and excluding alternative economies –even denying that

they exist". A social imaginary that becomes hegemonic makes it difficult to imagine its alternatives.

No other organization has been as globally influential in promoting the social imaginary of the knowledge economy as the OECD. This imaginary suggests that education is central to human capital formation for the development of national economies in the face of international competition and global pressures. Within an increasingly global economy, knowledge is assumed to be an intrinsic component of economic production and activity. The OECD has been centrally important in articulating and spreading this policy talk about the knowledge economy and the role education, innovation and research must play in it. Indeed, its document, *The Knowledge Based Economy* published in 1996 set the tone for the ways in which the knowledge economy is now described. Other international organizations such as the World Bank, UNESCO and the European Union followed its suit, as did many national governments, liberally using the concepts associated with the discourse of knowledge economy to develop their own policy recommendations.

The discourse of knowledge economy fuses various ideas about knowledge, information, learning, the economy and society into a single imaginary. Its claims to authority reside both in recent developments in the supposed facts of globalization and in recent economic theory, particularly new growth theory. According to new growth theorists such as Romer (1986) and Howitt (2000), in the era of globalization, economic growth is driven largely by technological progress or innovation that involves converting existing knowledge and human capital into new and improved knowledge products. In contrast to earlier economic theories, the new growth theory regards knowledge as endogenous to economic activity, requiring improvements in the ways in which knowledge workers and resources are used. It puts knowledge at the centre of economic policies, and makes investment in knowledge producing sectors such as research and education central to policy interventions.

Human capital development thus becomes a key to economic growth and competitiveness. As OECD (1996c) argues, "governments will need more stress on upgrading human capital through promoting access to a range of skills, and especially the capacity to learn." It suggests that the knowledge economy requires a larger proportion of workers to be prepared for highly skilled jobs, workers who have competencies to use new technologies effectively and favorable cultural attitudes towards change and innovation. In a rapidly changing world, these competencies include certain behavioral traits such as adaptability, organizational loyalty, and integrity; the skills of communication, information processing and problem-solving; the ability to work independently and under pressure, take responsibility for decisions and work in culturally diverse contexts, to seize upon the commercial potential of knowledge and to be able to work in teams and provide leadership.

In the knowledge economy, knowing about facts and theories is less important than an understanding of the world of social relations and the networks through which knowledge is converted into innovation and commercially viable products. This is considered more important than formal, codified, structured, and explicit knowledge. Against these assumptions, it is suggested by new growth theorists, such as Foray and Lundvall (1996), that a nation's capacity to take advantage of the knowledge economy

depends on how quickly it can become a ‘learning economy’. Learning, Foray and Lundvall argue, should not only involve the ability to use new technologies to access global knowledge, but should also mean using technology to communicate with other people about how to improve productivity. This implies that individuals, corporations, and nations create wealth in proportion to their capacity to learn and share innovation. If this is so then learning must be continuous and not restricted to formal schooling – that is, it must be lifelong learning.

Together these ideas constitute a new social imaginary, now vigorously promoted by the OECD, shifting the focus of learning from “knowing that” to “knowing how,” giving rise to new conceptions of the ways in which learning is defined, arranged, valued, and utilized in largely market terms. It represents an almost universal deepening of a shift from social-democratic to neoliberal orientations, in which economic goals of education are given priority over its social and cultural purposes. When represented as having a solid, almost incontestable, intellectual foundation, it does not permit alternative questions of value to be raised. As Kenway et al. (2006: 2) point out the discourse of knowledge economy does not question the values it promotes. They argue, moreover, that the “knowledge economy is haunted by the spectres of alternative economies,” because it does not examine how it privileges certain values over others, taking for granted its priorities, exclusions, contradictions, and blind spots.

In its popular form, the social imaginary of the knowledge economy imagines all human behavior to be based on the economic self-interest of individuals operating within free competitive markets. It assumes economic growth and competitive advantage to be a direct outcome of the levels of investment in developing human capital. It suggests that in a global economy, performance is increasingly linked to people’s knowledge stock, skills level, learning capabilities, and cultural adaptability. It therefore demands policy interventions that enhance labor flexibility not only through the deregulation of the market but also through reform to systems of education and training, designed to align them to the changing nature of economic activity. And it suggests a society in which economic concerns shape not only subjectivities and social relations but also governance structures. It encourages greater demands for accountability, surveillance, as well modes of policy coordination based on measurements of comparative performance, to provide information about the levels of global competitiveness.

The Rise and Rise of PISA

It is within the broader context of this social imaginary of knowledge economy that the enormous success of the OECD’s Programme for International Student Assessment (PISA) can be understood. PISA is based on a fundamental assumption that the international competitiveness of national economies is based on “the quality of national education and training systems judged according to international standards” (Brown et al., 1997, pp. 7–8). The OECD has been enormously successful in representing PISA as the most accurate and legitimate measure of comparative performance. Indeed, it has built a new policy niche for itself amongst international organizations for its

unmatched technical expertise in educational performance assessment. Published in its annual publication, *Education at a Glance: OECD Indicators and in other reports*, PISA demonstrates the important role that OECD now plays as a policy actor and mediator of knowledge (Henry et al., 2001), with an increasing capacity to shape policy priorities in education not only among its member nations but others as well.

As we have already noted, for example, UNESCO and the World Bank have drawn heavily on the OECD's expertise in developing the World Education Indicators for the education systems of the transitional economies. The OECD has also worked closely with the Commission of the EU in developing technical infrastructure for the collection and analysis of data of various kinds, including indicators, and has provided technical advice to numerous national systems. In this way, it has become a major international source of technical expertise in educational statistics. This expertise however privileges what might be referred to as "a number approach" to policy work, which sidelines the broader philosophical discussions of educational purpose, focussing instead on an input/output systems; attempting to offer policy insights about the efficiency and effectiveness of national educational systems.

In pursuing this technical approach to policy research, the OECD has been singularly successful in not only shifting the goals of the education towards the social imaginary of knowledge economy, but it has also been able to promote a particular notion of "good governance" in education, a phrase that masks an underlying shift in educational ideology. Located within the ideas of the new public management (OECD, 1995), which attaches a great deal of importance to the mechanisms of "steering at a distance" through comparative performance measures, the OECD has effectively shifted the focus of the educational governance from questions of purpose to such issues concerning transparency of decision-making processes, forms of devolution, technologies of measuring educational performance, international benchmarking, mechanisms of quality assurance, appropriate accountability regimes, sources of educational funding, effective uses of public resources, and so on. Even this short list shows how most of these issues relate to economic efficiency, defined mostly in terms of the extent to which educational systems are responsive to the labor market needs of the global economy.

Around the world, the effectiveness of educational systems is now increasingly measured against the performance data provided by PISA. Its results are taken very seriously by participating nations as a measure of the effectiveness of their education systems and the quality of their human capital, currently and potentially. Witness, for example, the apparent education policy panic in Germany following their poor results in the first PISA of 2000. The outstanding performance of Finnish students on all measures on all PISA testing to date has, on the other hand, made Finland something of a laboratory for educators looking to improve their systems. In each case, the categories around which the PISA is constructed have seldom been the subject of political debate, as comparative performance and relative rankings have assumed centre stage.

PISA was developed in the 1990s and was based on the 1999 OECD report, *Measuring Student Knowledge and Skills – A New Framework for Assessment*. It is conducted every 3 years to examine the applied knowledge and skills of students at the end of compulsory schooling at age 15 years. PISA tests the capacities of students near the end of compulsory schooling in the use of their knowledge and skills to meet

real-life challenges. Thus its tests are not curricula based; rather they are constructed in a purpose-built way by a contracted consortium of expert agencies with the support of technical advisory committees. A lot of sophisticated test development is done to ensure as far as possible culture fair testing and accurate translation. In this way, PISA creates its own data rather than drawing national data into a space of international comparison. PISA regards as crucially important its claim to comparability and a commensurate space of international comparison – a space of uniform measurement, or what Desrosieres (1998) refers to as a “space of equivalence.”

Within national frameworks; there was always greater concern about the creation of this national commensurable space than about construct validity, more about issues of reliability and comparison than ontology. The same is the case with PISA. It claims to have created a global commensurable space of measurement of the effectiveness of schooling systems in terms of the capacities of students at the end of compulsory schooling in the “application of knowledge to real-life challenges.” Its architects suggest that PISA is constructed in a policy relevant way and is concerned to ascertain the dispositions of students at the end of compulsory schooling for lifelong learning. As such, while there might still be some technical debates about the nature of the tests, most of the national and international media and political responses to PISA results are about the league tables of performance and comparative national positioning. In this way, the technical is privileged over the political, and the popular social imaginary of the knowledge economy is sustained. As Rose (1999) has argued, policy as numbers tends to do this – the power of numbers is such that they “render invisible and hence incontestable – the complex array of judgements and decisions that go into a measurement, a scale, a number” (Rose, 1999: 208). Arguably then PISA’s rise and rise would not have been possible without the social imaginary of knowledge economy complementing its central claims.

Rearticulating the Social

While PISA deals mostly with literacy, mathematics, science, and problem-solving (only in 2003), it also requires students to complete a questionnaire about themselves on their backgrounds, study habits, while background data on the school in terms of resourcing, size and the organization of the curriculum are also collected. This allows for the generation of some very policy-useful correlational data between variables such as socioeconomic background and performance, which has helped reignite equity debates both within the OECD members and elsewhere. However, as Berliner (2007) points out, the PISA’s technical focus means that its own analysis of equity matters is located within a very narrow definition of equity in education, as formal access to educational institutions. It eschews the broader political issues about educational justice, both within and across nations.

This is broadly symptomatic of the OECD’s general approach to educational policies. Indeed, while it would be wrong to assume that the organization is not interested in social and ethical issues relevant to education, it is equally true that, given its social imaginary of the knowledge economy, it views these issues within the broader

framework of education's economic ends. In this way, its exploration of such issues rests on what George Soros (1998) has called "economic fundamentalism," a kind of conceptual prism through which even such moral notions as equality are considered, with their meaning rearticulated. Equality, for example, is no longer interpreted as an intrinsic moral end as such, but is linked to the instrumental purposes of human capital development and economic self-maximization. So while the OECD continues to utilize seemingly ethical concepts, this work is increasingly couched in terms of such notions as access, social capital, and social cohesion, rearticulated in a language that views them as necessary for participation in the knowledge economy.

What such economic fundamentalism fails to do, however, is to recognize that access to education is a conceptually complicated matter and that a purely economic analysis of its character is never sufficient to realize the potential of education. So while a commitment to formal access to educational institutions is entirely consistent with the idea of economic efficiency, it is not enough to achieve social justice, more broadly conceptualized, concerned with the multiple and diverse ways in which human societies function. That this is so can perhaps be demonstrated by considering issues relating to the education of girls and boys. In recent years, organizations such as the OECD have repeatedly emphasized the importance of gender equity in education. And indeed much has been done to provide girls greater access to education; and the number of girls attending school has never been greater. In recent years, organizations such as the OECD have repeatedly emphasized the importance of gender equity in education. And indeed much has been done to provide girls greater access to education; and the number of girls attending school has never been greater; PISA results have been used to document the generally poorer performance of boys on literacy measures. The concern for girls has been about economic outcomes from schooling compared with boys in terms of income and career opportunities.

However, the arguments presented for gender equity by the OECD reveal its preference for a social imaginary that is cast largely in terms of economic efficiency, and the requirements of the knowledge economy. According to the OECD (2006), "Investing in women (with respect to education, health, family planning, access to land, etc.) not only directly reduces poverty, but also leads to higher productivity and a more efficient use of resources." Such an argument reduces concerns of gender equity to a purely economic logic, which is arguably sexist, since it views women as a means to certain economic ends, rather than as people who participate in education for a huge variety of reasons, some economic, others social and cultural.

A stronger claim to gender equity in education, on the other hand, would address issues not only of their access to formal education but also of social outcomes of their education, as well as the broader cultural issues of gender relations. Here the picture is decidedly mixed. Recent data show that while girls are participating in education in larger numbers than ever before, the benefits of their education are not proportional to their effort. For example, in recent years, there have been many more opportunities for women to utilize their education in paid work. However, this work has been predominantly in the service economy of global information, global communication, global retailing, and global finance (Scholte, 2000: 251). Each of these areas has been

characterized by “flexible” labor conditions and poorer career prospects, perpetuating and sometimes deepening gender hierarchies.

What this analysis indicates is that gender equity beyond access requires a radical overhaul of the educational and social processes that perpetuate gender inequalities. This aspiration is clearly informed by a broader purpose of education than that suggested by the OECD’s social imaginary of the knowledge economy, which, while it demands better utilization of the human resources that women represent, does not seek the social transformation through which gender relations could be reconfigured. For such a transformation, there would clearly be a need to highlight not only access and social inclusion, but also the importance of rethinking the terms of this inclusion. It would envisage societies that have potentially been economically, politically, and socially transformed in gender terms. It would require changes not only to the ways education is administered but also to curriculum and pedagogy, especially in the context of globalization with its potential to reshape patterns of both economic and social relations.

What is clear then is that the OECD’s interest in the social is largely driven by its commitment to the social imaginary of the knowledge economy. So, for example, its work on social cohesion is no longer promoted because it is morally worthwhile, but because it is necessary for economic sustainability and development. A similar logic is evident in the way the OECD has used the concept of social capital. Following Putnam (2000), the concept of social capital has received a good deal of attention within OECD circles in recent years. But, as Thomson (1999) suggests this interest stems from three impulses: a response to the dominant individualism underpinning the development of human capital for purposes of national competitiveness; a recognition that economic success requires a certain level of social cohesion, stability and trust; and a growing recognition that many people are decoupling economic success from sense of well-being.

In this way, social capital appears as a policy for managing economic marginalization, social exclusion, and heightening levels of cultural differences within societies, to promote social cohesion considered necessary for economic activity. But such a view of social cohesion presupposes economic efficiency to be a primary value, within the framework of which social and educational policies are couched. This effectively residualizes social concepts such as equality and social cohesion, no longer treated in moral terms, or as necessary for cultural sustainability, but essential for economic productivity. Educational policy, couched in terms of these concepts, thus assumes education to be a strategic tool for the management of economic change. Social exclusion is interpreted as a matter of failure to engage with the knowledge economy, either through the lack of appropriate skills or disposition or through the lack of effective governance, and not as a broader issue of social and cultural formations.

Conclusion

In this chapter, we have argued that a fundamental tension has always existed within the OECD between two competing perspectives on educational policy. The first of these perspectives views education in terms of its multiple purposes, as an instrument

of economic development but also a vehicle for promoting democratic equality and social mobility. This tension is accurately and insightfully described by Papadopoulos. For much of the period Papadopoulos worked at the OECD and discusses in his book, education was viewed in social-democratic terms, concerned with the development of democratic citizens, who could participate in their communities in a critically informed manner. Education was regarded as a public good, implying that maximum benefit could only be derived from education if every member of a community was educated equally to realize their full potential. The primary purpose of education was thus the creation of productive citizens. Economic outcomes of education were recognized, but were located within the framework of the broader role of education in the development of a socially cohesive democratic community.

We have argued that in recent decades this perspective on education has gradually given way within the OECD to an alternative perspective that emphasizes instead the role of education in ensuring economic efficiency within an increasingly globalized market. This perspective requires education to play an instrumental role in producing workers able to contribute to the economic productivity of nations and corporations alike. Its focus is not only on the needs and development of individuals but also on the efficiency with which educational systems operate. The emphasis is on the system's capacity to make an adequate return on investment, assessed in terms of its contribution in producing workers with knowledge, skills, and attitudes relevant to increasing productivity. In this way, education is viewed both as a public and a private good: public because it contributes to the economic development of a community; and private because it serves individual interests within a competitive labour market.

The ascendancy of this perspective to on education within the OECD, we have suggested, has been associated with a new discourse of globalization and its implications for educational policy. The OECD has justified this shift in its orientation in its educational policy work in terms of the need to reflect the changing global realities. In the process globalization has been reified, treated as if it is inevitable, with its various forms self-evident. Not only has the OECD's policy work been transformed in such terms the organization has also played an important role in globally promoting it. This has been done through the development of what we have called a social imaginary of the knowledge economy. Such an imaginary is based on the ideological belief that social and economic "progress" can only be achieved through systems of education more geared towards fulfilling the needs of the market in which knowledge has acquired greater importance than ever before.

With the purposes of education so instrumentally defined, education has been allocated the primary task of producing workers who have a grounding in basic literacy and numeracy, who are flexible, creative, entrepreneurial, and multiskilled, who have good knowledge of new information and communication technologies, and who are able to work in culturally diverse environments. Issues of social policy relevant to education such as equity and social cohesion are still considered important by the OECD, but their meanings have now been rearticulated to a consideration of the social conditions necessary for the development of these attributes and for economic sustainability and development within the global knowledge economy.

This ideological shift has led the OECD to a radically different view of its policy work in education, now concerned less with debating philosophical issues about the purposes of education and the sociological conditions in which education can serve its various purposes, and more with the technical issues of performance management, exemplified most explicitly in its educational indicators project, PISA. Ultimately, the OECD, which, in the Papadopoulos period, represented a unique forum for its members to debate educational issues has now become a policy actor in its own right, which promotes, through its ideological and technical work, a particular view of education concerned more with economic efficiency than with issues of social and cultural formations.

Note

This paper extends the work of an Australian Research Council funded project (1995–1997) conducted by Miriam Henry, Sandra Taylor, Fazal Rizvi, and Bob Lingard, as well as a book derived from that study, *The OECD, Globalisation and Education Policy* (Henry et al., 2001). The section on PISA also draws upon the project “Fabricating Quality in European Education Systems” as part of an ESF Eurocores project, in which the UK element is funded by ESRC (RES-00-23–1385). Bob Lingard acknowledges the contribution of his colleague, Sotiria Grek.

CAN MULTILATERAL BANKS EDUCATE THE WORLD?

Claudio de Moura Castro¹

This paper can be seen as a primer to educators who know little about the World Bank (henceforth WB) and the Inter-American Development Bank (henceforth IDB).² It tries to draw a broad picture of these somewhat mysterious and awe-inspiring organizations.

While both banks lend for a wide variety of sectors and the rules and principles are approximately the same, the paper focuses on education loans. One consequence of this narrower focus is to bypass the painful and inconclusive discussions about the choice of sectors where these banks should operate.

This essay is not the result of reading books and papers – even though some writings are helpful to better conceptualize the issues.³ The author has been an officer of both banks, as well as a close observer from the outside. This brings to the narrative a first-hand perspective and an effort to make sense out of a personal experience as an insider. There has been an earnest attempt to prevent personal interests and perspectives from contaminating his views. However, to claim neutrality in such matters is naïve, at best.

How Development Banks Work

The logic behind a multilateral development bank needs to be understood clearly. They are neither commercial banks, nor are they agencies funded and under administrative control of the rich countries (even though these countries wield considerable power in major decisions).

Their goal is to promote the economic and social development. After World War II it helped countries ravaged by wars. After the 1950s it focused their lending in developing countries. Perhaps at some moment in their history, economists thought they knew how to promote development. But history proved they were wrong. These days, all certainties about development recipes are gone. Therefore, such doubts compound the quest to find out whether they have been successful in their endeavors.

As should become clear in the text, no extreme views are warranted. Banks are neither a disaster nor an immaculate success; neither evil nor saints. They fail and they succeed. The gist of the presentation is to indicate some common denominators that have been observed.

Economic Rationale: Low Interest Borrowing

Let's start with a simple question. What is the financial magic performed by a development bank? In other words, in purely financial terms, what has justified their existence?

Several decades ago, a number of countries got together and decided to create a bank of their own so that some of them could borrow at lower interest rates. But even more important than that, borrow for long periods of time, such as 15–30 years. Hence, from day one they were banks owned by governments. Naïve comments about banks not being “democratic institutions” completely miss the target. They are democratic in the sense that their governance is exerted by a Board chosen by the member countries. Perhaps some countries have more power than others in this governance, but that is another matter.

Technically, they are not banks. They are more like credit cooperatives – where only members can borrow. Or, more precisely, credit cooperatives of participating countries.

How do they work? If the United States decides to borrow money, it issues bonds that pay the lowest interest rate in the market. Why? Because the country is rated “triple A” in the financial markets, due to the very low risk of default. Less developed countries have a much lower financial rating. Therefore, if they decide to float bonds, they will have to pay a rate of interest much higher than that paid by the United States, because borrowers are afraid the country will default on its obligations.

If the average Latin American country tried to borrow money today, it would pay interest that would include a considerable spread, to cover the risk of default. When the World Bank or the IDB float bonds in financial markets, they can do so at the lowest interest rate of the market. Hence, the whole idea of a “development bank” is little more than a market trick to allow poor countries to borrow money at rates that can be as low as half of what they could obtain on their own and with much shorter time to pay back. But in order to break even, the development banks have to add another percentage point in order to pay the salaries of the staff. And there is lots of staff, because this is a very complicated business. But since multilateral banks do not make profits, this in itself further lowers the interest rate.⁴

Therefore, the trick is to create a bank that includes the poorer countries that want to borrow and also the rich countries that lend their reputation and reliability. The credit worthiness of the big countries – the United States, Germany, Japan, the UK, and so on – permit the bank to have a “triple A” rating. This rating allows the bank to borrow at the lowest possible interest rate found anywhere in the world.

In contrast to what some people think, Banks do not lend their own money. They lend the funds they borrow. In fact, development banks do not lend rich countries' money. They lend the money they borrow from financial markets. Therefore neither the United States nor any other country is subsidizing the World Bank loans. The same goes with the IDB, or any other development bank. The United States, like others, contributed a modest amount of money in the beginning, to build initial capital reserves. Bankers know that just a little bit of capital leverages significant borrowing in financial markets.

Hence, in this respect, development banks are just like commercial operations; there are no subsidies involved. They borrow money by issuing bonds, and then they lend this money at interest rates that allow them to break even.

The downside of this operation is that banks have very little funds to make grants. In fact, it is easier for them to lend \$200 million than to give \$20,000 as a grant. Why? Because banks have as the only source of money what they borrow from the market. And if they borrow, they have to pay back. To be more accurate, they receive a modest amount of grant money from rich countries (lately, Japan has been the most generous donor) to selectively support a few projects. But the grand total of grant money is a very small proportion of what they lend.

The good news is that the banks have a lot of money. They can make a difference in many countries. They can add to the funds that would be available in public budgets an amount of money that a country would not otherwise have. In the absence of a loan, such funds would have to be subtracted from the salaries of civil servants or the provision of basic services.

Countries Have to Repay Their Loans, No Matter What

It is instructive to find that most professionals in the banks don't know much about the banking business. Ask anybody at the IDB or the World Bank about interest rates. Chances are they do not know. And there are good reasons for that.

Banks don't worry about repayment of the loans either. This is because if the country doesn't pay, it is put on the IMF's "black list." And being in this list is one of the most uncomfortable situations a country could be. It means that the country will not be able to borrow from any bank, multilateral or private. Perhaps even more important, the countries preserve their ability to have both the IMF and the WB as bankers of last resource, i.e., if worse comes to worst, they still have access to the funds from these two agencies.

This stiff penalty allows the banks to completely dedicate themselves to the lending end – or development objectives – of the operation. Bank officers worry about developing and implementing projects. In simple terms, there are no credit risks to worry about. Therefore, they do not behave like banks in the true sense of the word. They don't need to know about interest rates, repayments, or the like.

In many ways, project officers are neither the bleeding hearts who give money away nor the bankers who think only about interest payments and how to make money off someone else. Bank officers deal with development projects. They were recruited because their professional profiles suit them for those tasks.

Loan Preparation Takes a Long Time

Before development banks lend, they have to ensure that the money will go to projects that are fully spelled out, both in conception and in plans for implementation. There are good reasons for that.

Improvisation is avoided and the ideal conditions for implementation are planned, including all the precautions against corruption. The first step before a loan is a careful diagnosis of the sector where the funds will be spent.

The downside of this has to do with the fears of bureaucrats and their attempts to protect themselves against accusations of laxity and lack of control. In too many cases, the bureaucratic requirements go much beyond what seems like reasonable precautions.

Whatever the reasons, it takes at least 1 year to negotiate a loan and prepare the requisite contracts and documents. If there are disagreements between the Washington staff that is preparing the loan and the representatives of the recipient countries, it may take much longer. In the case of problematic loans or countries with ineffective governments, it may take several years to get it approved.

Strict Contracts Protect Loans from Political Vagaries

The good side of all the bureaucratic formalities is the stability and continuity that it brings to the programs funded by such loans. A minister can announce a program to be initiated the next day – to give milk to the children or to build schools. In 3 months' time, he may have been replaced by another minister announcing another program. Guess where the money comes from? Of course, from the program that was created 5 or 6 months earlier by the previous minister.

But change is not so easy with projects funded by a development bank. The country is committed. Contracts are signed. In other words, if both sides go through all the troubles to prepare and sign a project document, a significant amount of work is needed to get the project canceled. This is not a good idea. In addition to losing face, the loan funds cannot be used for alternative uses, because it is locked in this operation.

For decades, for every dollar included in the loan, the country Treasury had to put another (the exact proportion depended on the level of income of the borrowing country. These are the counterpart funds. One clear implication is that not only the loan contract was binding for the funds to be disbursed, but it also froze another chunk of money of the same magnitude.

Compared to the average government program, this inertia gives a much greater stability and coherence to the bank loans. They are more robust and have far fewer chances of being killed at the political whim of a new minister or a new administration. As a result, continuity, structure, discipline and technical support have a greater probability of presenting themselves.

Loan design reflects ample experience with similar loans in other countries. It represents the best practices known in the world, given the broad perspective and knowledge basis of technical staff.

Another advantage is that loans set aside an amount of money that allows a country to hire the very best minds in the world, which are expensive. Usually it is politically difficult for a country to hire such expensive consultants, particularly when local salaries are so low. But well-chosen experts can make a difference.

However, there is also a downside of this inertia. A bad project is difficult to change. Evolving conditions and circumstance would suggest new strategies that are not easy to implement. For good and for evil, loans have a great amount of inertia.

Why Development Banks are Accused of the Worst Sins?

Gone are the glorious days when the World Bank was merrily prescribing policies and lending, rather than stirring controversies. Today, some accuse it of being the satanic tool of “neoliberalism” while others complain that it is plainly ineffective. Bank officers wonder how they can be both at the same time. These days being a multilateral bank implies that you are criticized, no matter what you do or don’t do. “Fifty years is enough,” said the critics at the fiftieth anniversary of the World Bank.

The United Nation specialized agencies have been paralyzed by fear of displeasing member countries. In contrast, the World Bank always came forward with strong views and outright preaching on just about everything, from structural adjustment to contraceptives. As much as this was a relief from the wishy-washy positions of the United Nations, the collisions with governments and independent critics were inevitable.

Could this ideological rejection come as a surprise? Well, development banks are indeed strange animals. As a former employee of these institutions, we did not know whether we were gods, devils, preachers, bankers, arrogant civil servants with Ph.D.’s, or just hopeless and pathetic bureaucrats. Actually, we may very well be a mixture of all these.

Values and Beliefs

The accusations against the World Bank – and to a lesser extent to the IDB – have been persistent and, if anything, receive ever more press coverage. The days when they proudly announced their goals of wiping out poverty and backwardness are gone. In many ways, they now pay for their past arrogance, their hubris, and the obvious fact that they promised more than they could deliver. But that is not to say that the critics got it right.

The banks are often accused of being “neoliberal” – the worst insult in the lexicon of the left. Of course, it would be naïve to imagine that it is possible to have an institution operating in such central and delicate areas without an ideology. Neutrality and agnosticism are not options. To have any meaning, policies have to accept, deny, or qualify all-encompassing concepts such as free markets, private property, and public intervention. Therefore, implicitly or explicitly, banks do have their own ideology. The question is how acceptable this ideology is to the borrowing governments and to its critics.

The World Bank and the IDB still believe in some mild version of the Washington Consensus. But it is worth noting that this consensus is an ever-shifting notion. In addition, there is a huge difference in the strengths of such beliefs in either bank. The true believers have been in the World Bank, the IDB being far less religious and more pragmatic. However, stripped of all that has been added to this concept – by friends and foes – principles such as balanced budgets, paying your bills, and controlling inflation are goals that most countries accept these days. Notice that the original Washington consensus of John Williamson was not much more than that (Kuczinski & Williamson, Chapter 10).

Below is a list of the principles current in the World Bank that, in a way or another, influence education lending (in a toned down version, they are the same in the IDB).

- Evidence-driven policies (controlled evidence is the reality check)
- Cost accounting (one must know how much it costs)
- Quantification (the more one can quantify, the better)
- Efficiency (getting more done with less resources is a permanent goal)
- Meritocracy (the best are to be chosen and rewarded)
- Competition (belief in the “invisible hand”)
- Market incentives (rewards and penalties are the most powerful incentives)
- No subsidies (prices must reflect true costs)
- Privatization (private ownership improves efficiency)

Complying with some version of these principles was mandatory on most project documents, in order for the loan document to have smooth sailing inside the World Bank. At the same time, while the IDB was always driven by such principles, their defense was substantially less vehement.

Nevertheless, this is only the beginning of the story. Thinking in either bank is far from being monolithic and compliance with the ideological impositions is more formal than real. Many loan officers added to their proposals all the mantras of the moment, knowing full well that they were not enforceable. Why fight for ideas that will never get out of the paper? It was more expedient to get the project approved quickly and then proceed to implementation, where realism prevails.

The idea that bank professionals form a disciplined army, thinking alike and implementing official policies is naïve. This could not happen in an institution that hires the top graduates of the world’s best universities – with analytical skills honed in debates and controversies. In fact, attending technical meetings in the WB one cannot escape the conclusion that professionals enjoy showing off and fencing with one another about theories and policies, more than anything else. There is a wide range of opinions and policy orientation among professionals and a lively debate goes on all the time. But in matters considered as serious, there is far more than intellectual legerdemain. In fact, as reported by Heyneman and witnessed personally by this author, during the first half of the 1990s, the doctrinaire clashes between education professionals, division chiefs and the management of the bank were nothing short of formidable (Heyneman, 2003).

Decision Making: How the World Influences the Banks?

To understand the logic of multilateral banks, it is useful to have a brief discussion of how decisions are made. Bank policies are generated in the interplay of three main actors: (i) management and staff, (ii) the Board, and (iii) the outside political forces that have a say in these matters.

Notice that banks are well-staffed at all levels. It has been said again and again that no other agency in the world has such an intellectually powerful and experienced staff in matters of development. In fact, no other contender stands up at the same league. The mindset of the banks is a natural consequence of the academic origins of its staff.

It comes predominantly from the very best universities, with a strong participation of graduates of leading Anglo-Saxon institutions. Therefore, ideas spontaneously reflect mainstream economic traditions. Not surprisingly, intellectual arrogance and hubris often comes in the same package. Ideological and theoretical beliefs derive directly from these academic origins. Bank practices acquire a style of their own but they rarely collide with the tenets of classical economics.

Banks operate in a political world and cannot ignore it. The WB members include just about all countries in the world. The IDB includes Latin American countries plus most rich and large countries – as mentioned, their presence ensures low risks and low interests for the funds it must borrow to make available to in the form of loans to member countries.

In practical terms, the United States (via the Treasury Department) has a disproportionate power. Being the largest shareholder, by the constitution of the Bank, it has more voting power. Presidencies or vice-presidencies are tacitly allocated to Americans. In the past, there have been the tugs of war between the United States and other countries. Today, in the majority of the cases, American positions do not go against the grain of most other member countries. But there are exceptions. For instance, indirectly, the United States has been able to prevent the entry of Cuba, both in the WB and the IDB. Yet, it failed in its attempts to save the presidency of Paul Wolfowitz, when accusations of nepotism surfaced.

North European countries take a strong stand for the environment, minorities, Indians, and the very poor. At times, it clashes with borrowing countries that may want to remain reckless in these matters. In other situations, borrowing countries find that they are too poor to impose strict Scandinavian standards. And they may be right.

NGOs' themes are similar to those of the Scandinavians but tend to be more strident and radical. At first, their whistle-blowing played a useful role. But they seem to have gone too far, after banks got their act together in those matters. In addition, there is an increasing perception that some horror stories were not true. Particularly in the case of the WB, NGOs have put much pressure to have a greater say on the lending operations. In fact, some of them are clearly antagonistic to the very existence of the banks. The "Fifty years is enough" campaign was very troubling to the WB, to the point that the commemorations for its half century anniversary were severely curtailed. Washington is a sounding board for NGOs and they are able to create much noise. This is a very contentious situation, as the noise created by hundreds such institutions bring a bad press for the banks.

Finally, borrowing countries are entitled to have a voice. Why not? At first, the rationale was much in the line of the "white men's burden." Poor countries were thought to be disorganized, have ineffective and corrupt governments and lack good judgment on what is good for them. But progressively it has become politically inappropriate to pursue this line. In addition, many countries have a clear and sound idea about their needs and preferences. In more recent years they do have a louder saying in deciding on their loans. It took some time to realize that when borrowers take ownership of the project, the chances of success are much higher.

These political constituencies have had an oscillating role in influencing the policy orientations of the banks. For instance, specific projects to deal with one aspect of development or broad, all-encompassing development policies?

Resulting from the interplay of all these constituencies, the banks developed their policies and styles.

Leftwing Educators Battle “Neoliberal” Values

The supra-national agencies such as the IMF and the World Bank ... [are] like a kind of economical and political ministries of transitional capital. ... They are the lords of the world or the *de facto* power in the world. (Frigotto, 1995, p. 82)

... all this [education development] is being orchestrated by the World Bank with its concept of education systems linked to vocationalization, aiming at preparing individuals to meet the requirement of productive activities and market circulation. ... (Ianni, 1996)

There is a growing participation of outside economic agents – the World Bank and the Interamerican Development Bank – as well as local entrepreneurs. (Monteiro, 2000, p. 48)

Sector Analysis documents of the World Bank, in general, display a lack of understanding and inadequate knowledge of education and accumulated research in the field. ... The dismantling of Education Ministries is, to a large extent, the direct and indirect result of the World Bank and IMF packages ... The World Bank ... package presents serious shortcomings ... and instead of contributing to change in the proposed direction ... reinforces inefficiency, poor quality and inequality in school systems. (Torres)

The above quotes illustrate the kind of opposition met by multilateral banks. Most of them have one feature in common. They reflect little knowledge of institutions and result from very cavalier research.

Let us look at a very instructive example. A book by a well-known researcher in Brazil bitterly denounced the World Bank for having master-minded the reform of technical education, by means of a loan to the Ministry of Education. She went on to describe how this foreign institution was interfering in domestic educational policies (Kuenzer, 2000). As it turns out, she did not take the time to verify that the loan was from the IDB not the World Bank! In fact, the World Bank never lent for technical education in Brazil. Furthermore, it was denouncing policy changes originally proposed by the author of this essay while he lived in Brazil, 10 years before he joined the World Bank and the IDB. Subsequently, when the loan to Brazil was being designed, this idea was introduced in the loan by this author who was part of the project team. Therefore, the supposed interference by a foreign power was merely an old Brazilian idea proposed by a Brazilian staff.

NGOs’ Fight for Influence in Decision-Making

From the 1990s on, NGOs claimed increasingly greater power to influence and to veto loans to developing countries. This has been particularly true in loans where environment issues were at stake.

It is a documented fact that some dams proposed by the World Bank were environmental disasters. And it is to the credit of watchdog NGOs that such reckless projects were denounced. In part due to such criticism but also as a result of a greater overall awareness towards environmental issues, the Boards reacted by imposing a severe environmental screening, since the early 1990s.

Notwithstanding, the NGOs toned up their criticism. The whole issue became somewhat muddled, as the NGOs kept repeating the criticism levied against old projects, since there was little to criticize in the more recent crop. This led to bitter confrontations after bank projects became very careful along the lines of protecting the environment. In fact, some loans imposed unreasonable increases in expenditures on the projects, in order to avoid some minor problems (for instance, to protect a small monkey from a road development in Brazil). Ultimately, in deciding the fate of a large loan, angry activists can wield more power than some major countries.

The whole issue seems to have gone overboard. One ridiculous example was a small project by this author to conduct student-achievement tests in ten Latin American countries. The preparation of the project was delayed by requests of one participant in the environmental clearance board. This person wanted further assurances that applying tests to a few thousand students committed no sins against nature.

How Development Banks Design and Negotiate Loans

In order to understand the operation and the logic of development banks, it is useful to examine how loans are prepared and negotiated.

What Governments Want, What Countries Need and What the Banks Want to Sell

When the bank sends a project officer to negotiate a loan, this action mobilizes several actors and lead to the discussion of a complex and sometimes contradictory set of goals. It is useful to try to understand the typical scenarios.

Bank officers have development goals in their minds. Typically, they honestly try to analyze the situation and derive the policies that would be most helpful to the country. Critics may deny such lofty goals. Hypocrisy? Fake idealism?

My own experience of 10 years inside both banks leads me to believe that my colleagues meant well and did know their line of business. They try to design projects that respond to what they perceive as the legitimate needs of the countries. Of course, they can be dead wrong, but that is not the issue. In some cases, they may be indulging in what is called “cookie-cutter projects” that repeat solutions tried elsewhere. But that is not the predominant situation.

In fact, professionals tend to be moved by an earnest sense of duty in the search for the best policies. In principle, they propose what they see as the ideal solutions to the problems faced by the country. Their most egregious sin is to ignore institutional barriers to implementation, such as the presence of politically strong opposition to some dimensions of the project. In this sense, the project may be unrealistic, because it proposes to do more than is politically possible. But staff means well.

Program officers do not have “the country” as counterpart. Instead, they deal with ministers and those representing them. The Minister may be easily persuaded that what is proposed by the Bank is what his country needs. Low and behold, Ministers are politicians who have as their number one priority, survival in the position. As mentioned by the French Minister Luc Ferry, many appointed ministers believe that they have been given a horse, in order to go somewhere. But it takes little time to realize that they are in a different sport. They are in a rodeo and the goal is not to fall from the bucking horse.

Therefore, what is good for the country may be politically impossible, may cost his job, or erode his political capital. What most impressed this author in many missions to discuss direction and content of loans was this ludicrous situation in which a foreign representing a bank defends the real interests of the country while the Minister is concerned with the arithmetic of power. But there is nothing evil in the Minister’s behavior. It is just the game of politics.

If there is a frank dialogue, the Minister may be candid about his predicament. In common accord, political means to make the project more palatable to its adversaries may be sought. Very often, it is agreed that the blame for including this or that item will be put on the Bank, the Minister playing the role of a passive victim.

Economic Rationality or Political Feasibility?

Practical economists and bank officers very often face a severe trade-off between what is the best economic solution and what is politically feasible in a given situation. In order to understand that, one needs to follow the ups and downs of how decisions were taken by banks, along their history.

The World Bank was born as an institution to fund the reconstruction of an Europe ravaged by World War II. It was a brick and mortar bank and it did not need be more than that. All that Europe required was to rebuild its physical infrastructure.

After having done that, the WB moved on to lend to less developed countries, all around the world. Sooner or later it became clear that these countries needed more than buildings and roads. Their institutions were in severe state of disrepair.

In the 1970s, the World Bank added institutional reform components to its loans. The idea was perfectly sound. But its implementation turned out to be far more ridden with problems than imagined. The results were not very good. The relations with clients became very confrontational and, in many cases, little reform was achieved.

At the same time, the IDB went on with simple loans to construct and equip. Little was asked in the line of reforming institutions. These loans were far more successful. They were easier to implement, even though the serious problems – mostly in dysfunctional institutional settings – remained untouched.

In the 1990s, the IDB modernized and became more concerned with reforms. At the same time, the World Bank softened its demands for institutional changes – after having seen so many projects stalled. Progressively, the two banks became more similar in the way they operate. In a few extreme cases, the IDB became more reform-oriented

than the World Bank. But overall, they are still different banks. Let us examine a picture that is far too exaggerated.

The World Bank approaches the countries with elegant solutions to their problems. It does its homework and produces sophisticated papers analyzing the issues and proposing creative and well spelled-out schemes. When the time to negotiate comes, it tends to be prescriptive and to insist on its own elegant views. Quite often, the project officers do not know well the country, its politics, its bureaucracy, and power structures.

Countries that are less able to defend their ideas succumb to the pressures of the World Bank and accept the loans as proposed. Several outcomes are possible. In one scenario, the loans are not implemented. In others, little in terms of reform takes place, despite great consumption of energy on both sides.

Another scenario is when the Bank staff meets well-prepared and assertive government staff on the other side. Sharp disagreements may ensue. Such countries are forthcoming in what they want and they stand behind their ideas. But once agreement is reached, after much give and take, there is a much better chance of successful implementation.

IDB style tends to be different. It goes to the country and asks the Minister what he wants. Its officers know better the country and its institutions. And they always speak the language. Several outcomes are possible. In one scenario, a very simple loan is proposed, foregoing the potential to achieve something else in reforming institutions. In more favorable scenarios, politically viable reforms are negotiated with the Minister.

The above is a simplistic and exaggerated description of either bank. But for this reason, it helps one to understand the tone of the negotiations and the differences between the two banks.

But in addition to all those considerations, purely personal elements and circumstances – on both sides – play a role that is far greater than anyone wants to admit. Project officers end up having much leeway in negotiations. They are relatively free to fine-tune the projects or to make blunders.

A skillful officer has a refined perception that allows him to go as far as possible, but not farther, in insisting that this or that feature be included. He knows whom to trust and he knows where the real power is.

A clumsy or arrogant officer may clash with his counterparts and insist on what is not politically possible. Bad choices can be made.

By the same token, local staff makes an enormous difference. Here is one example. The IDB and the WB prepared two similar education loans to Ecuador. The IDB went to the rural sector and the WB to urban marginal schools. The WB was a great success. The IDB project never really functioned properly. The reason had to do with the excellent local manager of one loan and the unfortunate succession of mediocre managers of the other project.

Conditionalities: Powerful, Potentially Useful But Dangerous

Let us now examine what is the most delicate part of development banking. This is something called conditionalities. It reminds us of Teddy Roosevelt, when he proposed to speak softly and carry a big stick.

Loans may have strings attached. Conditionality thus means that the country must fulfill a certain number of requirements in order to get the loan. For instance, reforming teacher statutes, reducing deficits, charging full costs of utilities, preserving the environment, or whatever is fashionable at the time. In the majority of the cases, conditionalities will have two key features: (i) They are good for the country – at least in the long run (ii) and they carry political costs to incumbents that must implement the reforms.

Ideally, a conditionality uses the clout of the Bank and the massive volume of funds it has to offer to push through reforms which, most informed citizens agree, are welcome but politically costly. Therefore, they probably would not be undertaken if not backed up by bank pressure.

This puts a frightfully dangerous weapon in the hands of the banks, but it is a most formidable weapon for pushing reform. It allows a Ministry to overcome political opposition or inertia. Conditionalities give the banks the power to be a catalyst for reform.

However, past experiences with conditionalities have taught very humbling lessons. First, things can go wrong. Second, to be quite frank, the banks cannot impose reform. This was the painful lesson the World Bank learned in the 1980s, when as much as one third of its portfolio was underperforming.

Why? Because the Bank tried to impose loans and reforms by brute force. We need to be very clear about this: Banks cannot reform. They are pitifully weak in this regard. The picturesque expression “herding cats” has been used to describe those failed efforts.

However, banks can be catalysts for reforms that are close to happening. In order to achieve that, they should have good antennas to find where reforms are brewing. Along these lines, the best they can do is to find the good guys at the right moment and support them in their efforts to make reform happen. The education reform of the State of Minas Gerais (Brazil), in the 1980s, illustrates this successful strategy. A strong leader with considerable experience in education became State Secretary of Education and pushed for reform. A WB loan made implementation much easier.

Conditionalities in Action (or Inaction?)

Since conditionalities are the most critical and contentious element of a loan, it is worth offering some concrete examples. Cases were chosen due to the author’s proximity to them and to illustrate the variety of possible outcomes.

Let us start with one of the worst scenarios. The political price of reform may be excessive and the advice ill-conceived. Bolivia accepted a reform that imposed tests for teachers and eliminated the tax that funded their unions. When the government tried to implement these policies, this created such a political turmoil that the country went into state of siege. This conditionality was a bad idea.

Paraguay contracted a very elaborate loan with the IDB, in order to reform and support vocational training. The loan had two parts. One went to an executing agency that set up a competitive fund to train employees of small firms. The firms received training vouchers for their staff that could be used in any of the approved private schools. This segment of the loan was a great success. The other part of the loan, much larger, was directed to the national training authority. But it was contingent on several structural reforms in an institution that was undergoing a severe crisis. Years elapsed and the second part could never be implemented.

Morocco took a WB loan to construct technical schools and to undertake some structural reforms in their system. The technical schools were built and became an instant success. But the loan also prescribed that part of the budget of the Office de la Formation Professionelle was to be redirected to a fund, in order to invite competitive bids from private training institutions. Years went by and, in every visit, the officer of the WB would meet the Minister and ask about the creation of the fund. The answer would be predictably evasive. Of course, it goes against the grain of civil servants to take away from their own budget to fund private schools. The condition imposed was unrealistic to start with.

Brazil wanted a loan to fund technical schools. But the predicament of these schools was that they offered an academic education of the highest quality, parallel to the occupational training. As a result, upper class students would bid out the more modest students in the competition to enroll in the technical school. But all the selected students were interested in was, once graduated, to get approved in the most competitive examinations for higher education. The other students who could have an interest in the occupations taught would be left out. For all practical purposes, the expensive occupational training was a complete waste. The IDB imposed as a condition for the loan that the technical schools were to be split into two separate programs: the academic secondary school and the occupational training. Therefore, upper class students would not be interested in enrolling in the vocational track. They had all the good reasons to choose only the academic program, leaving vacancies in the occupational track to students who really wanted this type of courses. The Minister welcomed this condition. For him, this was the right thing to do and he had the power to face the political opposition. However, when an IDB executive tried to propose that the secondary track be closed, this was a non-starter. The Minister simply said no. Here is an example of a condition that was agreeable to the Minister and was met. The other condition was unacceptable and was discarded during negotiations.

Are Loans Effective?

The ultimate criterion in judging the role of multilateral banks is to check the result of the loans. This is the end, everything else is the means.

Who Benefits?

By looking at the performance of loans, one should be able to derive some generalizations about the profile of those countries that benefit the most and those who get little out of them.

It is curious to notice that despite an incredible volume of papers and documents produced by banks, relatively little was done to gauge the effectiveness of loans and their ultimate impact on development. Matters have improved considerably in the last 5 years. But it does not seem that the present situation is entirely satisfactory.

Loan procedures follow very predictable and spelled-out procedures, both to prepare and to manage during execution. Nothing is left to chance. And to wit, on both stages, this is a very complex and demanding work, putting a very heavy burden on public

bureaucracies. In fact, first-hand experience shows how painfully slow and inadequate is their delivery of services. Given the shortcomings of most public bureaucracies, we know full well how painful is the burden created by these requirements. Therefore, it is not a surprise that the weaker the civil service, the more excruciatingly slow is their operation. It follows that the execution of the loan will be harmed.

It must be noted that even in the same country, some ministries are alert and efficient while others are ponderous and unable to deliver. Hence, bank officers must evaluate each bureaucracy and gauge its ability to handle the loan.

What Can Go Wrong with Loans?

Projects in the social area can go wrong in many possible ways. Unless they are mere physical infrastructure operations, social projects are complicated and depend on the adequate performance of a multitude of agents who cannot be directly controlled. But from the point of view of this paper, let us examine the following typical problems.

Disbursement delays are the most conspicuous difficulty and the easiest to understand and measure. The cash flows, automatically monitored by bank accounting, capture many of the difficulties and shortcomings that may suffer a project. In other words, anything that goes wrong usually delays disbursements. It could be waiting approval in a slow-moving Congress. Until some years ago, delays in counterpart funds were a most recurrent problem (more recent loans dispense with them). Or, the executing group is not efficient. These are problems that tend to be purely administrative and reappear frequently in projects that have very little in common.

All such snags converge to a single result: money is not disbursed and the timetables are not met. And the more complex the loan, the more difficult it is to implement. While this author does not know any systematic research on this subject, first-hand observation suggests that countries known for their weak bureaucracies tend to have loans that do not perform or are delayed.

The same applies to different ministries. Loans that perform well in one ministry tend to be followed by other successful loans in the same ministry.

Of course, there are accidents, such as the loss of critical officers managing the loan, on either side. Contrariwise, problem-loans can be fixed and fine-tuned to perform splendidly. An extreme case is an education loan to the northeast of Brazil that took 10 years to really get it working well.

Reform-intensive projects are the most vulnerable loans. Even in poor countries banks often do well in building infrastructure. They overcome the bureaucratic weaknesses by hiring international firms that know the business of building bridges and railroads. School or hospital construction is usually subcontracted to the private sector. But problems appear when banks try to tackle more complex development problems, such as reforms that change the way people and public institutions work.

When banks try to go beyond heavy infrastructure and help the poor in poor countries, this may turn out to be impossible. Such projects require a level of bureaucratic robustness on the receiving end that is rarely – if ever – found. Programs to help the poor must break down the resources in very small parcels that will go to a multitude

of small institutions. Controlling this complex web of transactions is a nightmare. This is the case with rural schools, health posts, distribution of milk, or whatever requires capillarity to reach the bottom of society.

Sometimes, bank staff cannot even prepare loans because the bureaucracy on the other end is administratively weak and cannot present background data and statistics. When the loans are made under such conditions they often end up being failures or bad projects.

To sum it up, banks can help the very poor in middle-income countries. But they have too often failed in trying to help the poorest of the poor in poor countries. This is an unfortunate contingency.

In recent years, both banks have become less arrogant and more humble, learning to be more careful in adjusting the projects to prevailing conditions within countries.

The World Bank has tried to sell reform time and again, particularly in the 1980s. More often than not, it has not worked. It used to be that designing a modern reform project was a challenge for bank staff. Now, staff in both banks knows how to prepare such projects. The real challenge is to understand the country and to know how far it can go in reforming its institutions.

In conclusion, development banks do have something to offer, even to poorer countries. But it has to be tailor-made for each case. The good news is that they are learning their lessons.

However, banks cannot escape from a serious predicament. The better off the countries, the more effective and reform-oriented can be the loans. And the poorer the countries the more they need reform and the more difficult it is to help them. Let us consider, for instance, that some of the recipient countries have fewer phones than the offices of the WB. Or, countries in which horse-drawn plows represent a technological innovation (Mallaby, 2004: 342). In other words, those who need the most are the ones who can benefit the less from the multilateral banks – at least, the way they are organized nowadays. Worse, even at the design stage, no better solutions have been found for funding development in these poorer countries.

Ultimately, too much depends on the internal dynamics of the country. Banks are unable to alter it significantly. If the country cannot get its act together, loans are likely to perform poorly and have little impact on development.

Managing Loans: A Nightmare of Paperwork

Banks are not as evil and incompetent as their nemesis denounce. That, however, is not the critical issue. In fact, most accusations miss the target. They focus on policies and policy controversies and usually fail to notice the most critical weakness of multilateral banks: the implementation stage.

Outside authors, both right and left, focus their comments on policies, policy debates, and the intrinsic merits of what the banks are proposing to do. Yet, to my understanding, this is not where the real problems are. How useful is it to discuss endlessly the ideological soundness of a proposal to reform teacher regulations if all the countries can implement is the construction of schools?

Past experience has taught the banks very humbling lessons. First, everything can go wrong – and things do go wrong. Banks do not advertise much their failings at the implementation stage. Some projects die at the preparation level, due to the inability of the country teams to respond to the requests for information or due to basic disagreements about what the project should look like. A few are approved but never disburse, due to legal snags or bureaucratic inertia. Most loans actually disburse but slower than predicted. In fact, very few loans come to completion within the originally scheduled program. A significant proportion gets stuck somewhere along the line, due to many different reasons, the major one used to be delays in counterpart funding. A cycle of 15 years is not uncommon.

The fact of the matter is that loans have very complex disbursement mechanisms and accounting, since banks and the local government share costs and responsibilities. Bureaucratic controls to avoid corruption and embezzlements slow down everything.

Evaluation has Unclear Impact on Design and Procedures

In all fairness, banks have departments that have as their main task to evaluate past performance of their loans. Some of the papers produced are well prepared and candid in their appraisals. However, banks are not too eager to disseminate statistics showing which projects fall victim of each of the problems already mentioned.

The fact of the matter is that all the internal incentives to find out and denounce projects that did not do very well are quite dim. All parties concerned stand to lose. Perhaps this is the weakest link in the entire system.

Ultimately, one would want to know whether the loans achieved their purpose. This, of course, is a thorny issue, not very popular among bank administrators. Not only that, but agreeing on what is the purpose of the loan is just as delicate. There are several measures of achievement. The one favored by current bank procedures is disbursement. Lack of disbursement is the only real embarrassment for bank staff.

The failure rate, measured as not disbursing all the money in the loan is relatively low. It used to be 10% in the IDB. But even though the vast majority of the projects eventually disburse all the funds and come to an end, the delays are recurrent and serious. It is not uncommon for a project to take more than twice the planned time to be executed.

Once the money is disbursed, there is a sigh of relief and few want to probe further. The next step, also formalized in the banks' rituals, is whether the money purchased what it was supposed to purchase. In other words, was the prescribed number of schools built? Were all the targeted teachers trained and the books purchased? This is part of the contract and is duly verified by accountants and auditors. But this is tantamount to measuring results by measuring inputs.

The issue is not whether teachers have taken courses. But have they learned anything? Are the students benefiting from their increased skills? We often know that the purchased books were distributed. Perhaps we can find out whether they are being used. But are students learning more as a consequence?

Loan officers and the bank bureaucracy rarely, if ever, ask these questions. But ultimately, they are the truly relevant questions. Otherwise, why have loans if students do not benefit from them?

To be fair, special studies by evaluation offices of the banks do ask such questions. And they are becoming better and increasingly frequent.

Low and behold, the results, while not tragic, tend not to be very flattering. The bureaucrats pay attention to the papers and attend seminars organized by evaluation offices. They politely acknowledge the results, agree on their importance and do nothing about it. Given the existing rules, there are no rewards for doing much along these lines. Nobody gains by admitting that loans have less spectacular impacts than assumed by the standard rules of measuring results. And finding culprits of unknown sins is not good form among peers.

Probing a bit deeper into the realities of implementation, there is one recurring result that is often mentioned by observers – mostly inside the banks. The less physically concrete the line of activities, the greater the chance of not being implemented. Typically, all schools are built, most teachers are trained and computers are purchased. Also typical, the reform component is not implemented.

Are Banks Learning Organizations?

After so many years of doing projects, it is fair to ask whether banks are learning from their experience and from their mistakes. In other words, are they learning organizations?

This author and an associate (from the IDB) have conducted an analysis of the entire IDB portfolio of education projects, asking exactly this question. The paper was never published, which is understandable, considering the sensitive nature of the material. What is worrisome, but not surprising, is that it never received much attention from the management of the Bank (even though it was widely requested and read by staff) (Castro & Verdisco, 2000).

The results are surprising in more ways than one. Firstly, they are clear-cut, which is not common in such analysis. Secondly, they show a sharp dichotomy in the answers that were found to the basic question asked.

When asked whether a new project reflects what was learned in the previous loans along the same line, the answer was clearly positive. Each project tends to incorporate learning and lessons from the previous. The IDB tends to repeat success stories and tries to fix problems found in previous projects that are similar. Hence, in this sense, the IDB is a learning organization.

However, when we looked at implementation, the answer is just the opposite. The tools of implementation are cumbersome and do not seem to improve. What did not work before in managing and controlling projects reappears again in the next one. The same mistakes are repeated again and again. The projects get stuck exactly in the same hurdles (lack of counterpart funds, poor management, lack of leadership, bureaucratic snags, and many other recurrent causes).

Offering management-training programs is naively taken as administrative reform or improvement. Local control procedures are too complicated. Fear of corruption traumatizes small bureaucrats who would rather slow down a project to a halt, rather than run the risks of petty irregularities. Supervision is purely from an accounting point of view, failing to notice obvious errors of judgment along the way.

What is worrisome is that these weaknesses do not generate any counterforces to fix the system. There is great inertia in the system. The banks are not learning organizations in what concerns implementation. They are stuck with dysfunctional procedures, fail to detect problems, fail to fix them, and fail to create any meaningful motivation to learn and use this learning to improve design.

Ideas or Funds?

Late in the 1990s, the WB management floated the theory that it should go into the business of helping countries with ideas, papers, and policy suggestions, instead of lending money. In addition to loans, it would become a huge consulting firm. After all, the technical competence of the WB is peerless.

This proposal seems a good launching pad to discuss the reform components of loans. Are there the good ideas that the banks could provide to countries? Would countries pay for them?

We cannot go beyond conjectures and subjective perceptions. But for what they are worth, it seems to this author that these ideas will never fly. Ministries do not seem particularly motivated to contract expensive consultants to propose reforms that are politically painful. And most reforms are painful.

Let us not forget that other international agencies, such as UNESCO, are prodigal in advice to member countries. And it is quite clear that countries do not pay much attention to what they propose, even though the ideas come free of charge.

Experience seems to suggest that one big and real motivation to engage in reforms is the large sums of money that come with the loans. Therefore, what sets banks apart from other international agencies is exactly the fact that the funds provided by the loans, somehow, force the Ministries to pay attention to the policy suggestions. In fact, the conditionalities – mentioned before – are just the mechanism to obtain the implementation of the policies proposed.

Small countries – or those that are very anxious to get a loan, in order to have more slack in their budgets – are the ones that tend to take the advice more seriously, particularly when they come as conditions for the loans.

More affluent countries are in a better position to resist conditionalities that have a heavier political price tag. Take the case of Brazil, where the national development bank lends three times as much as does the WB to the entire world. In fact, WB loans in Brazil will not buy a reform that is needed but politically uncomfortable. If the country undertakes a reform, it is because the moment is ripe, not because of the loan contracted with one of the banks.

Having said that, it is also necessary to recognize that banks are powerful and creative proponents of new and valuable ideas and policies. Hundreds of professionals and an even greater number of distinguished academics are engaged to do serious research on most areas in which the Bank lends. The close links with the academic world give a strong credibility to the ideas disseminated by the WB – and to a lesser extent, by the IDB.

In fact, many ideas that acquired currency and legitimacy were originally proposed by them. This is the case of testing students and using the results to evaluate progress in education. The same can be said of the emphasis on high-quality textbooks and teaching materials, as well as computers. Ideas on health and social security reform

originated in the WB. They were at first rejected but eventually, were successfully implemented.

In this respect, it is interesting to notice that new ideas take long to mature. The first paper on health reform came out more than 10 years before the first country adopted it – to wit, Colombia.

Another wild card in this game is that ideas change. Cynics may claim that they are subjected to the same vagaries that determine feminine fashion. The World Bank and the IDB pushed higher education vigorously. Then, they decided that there was over investment in universities and the crisis area was basic education. No more lending to higher education for over one decade and a barrage of papers denouncing the mistake of putting money in universities – even though, often the money came from the banks. Now higher education is back in fashion.

The question that comes to mind is the inevitable doubt about the impact of new ideas versus the impact of the loans in the long run. One could argue that good ideas eventually become acceptable and implemented, while loans tend to merely build schools or equip them. As much as this is a critical issue, it does not seem that we have good evidence to clarify matters.

There has been much discussion on matters of ideas versus money, particularly in the WB. In part, they have been prompted by outside critics that tend to exaggerate the power of multilateral banks. Yet, some observers have a much more sobering or even pessimistic view. For instance:

World Bank funding exerts little influence on social policy. ... High concentrations of World Bank funding have virtually no impact on the share of educational resources devoted to primary education. ... Although the World Bank has the financial resources and the technocratic allies to buttress the transmission of its ideas, bureaucratic and political forces often get in the way. ... In the final analysis, the World Bank can pressure but cannot force the Brazilian government to adopt its recommendations. ... Domestic political forces prevail over international technocratical linkages when it comes to redistributive social policy making. (Hunter & Browne, 2000)

Be that as it may, in the long run, ideas and a better understanding of problems may very well be the most important contribution of development banks. But they take long to mature.

Lessons?

There has been mounting criticism levied against the Banks (as always, the WB is the main target). Much of it is heavily ideological. Some is just the visible manifestation of interest groups, in their efforts to influence the bank lending and policies.

Our central contention is that most criticism is misdirected. The egregious shortcoming of the banks is the fact that great ideas succumb in the process of implementation. Countries just cannot implement the projects funded by the loan. But the banks are just as guilty, because they misjudged the implementability of the loan.

At first, life was easy, countries badly needed the loans and were not ready to take an adversarial stand. But more and more, strident critics from the left began to criticize the

banks, both in the advanced and in the less developed countries. Banks were accused of being an arm of imperialism and to impose their ideology on borrowing countries. These indictments often have a grain of truth but are largely unwarranted as attempts to disqualify almost everything the banks do. The argument here is not that banks are entirely innocent. They are not, but the critics tend to miss the target.

The ideology that stands behind bank loans reflects what Western mainstream economists believe. Surely, there are dilemmas. For instance, more growth with larger deficits and inflation? Or a more conservative financial management? More reform or more bricks and mortar?

Be that as it may, only a few of the bank loans are contentious. It seems that minimally rational critics could find little to complain about the average loan. Who can be against roads or hospitals in the case they are truly needed?

As someone who has had significant contact with those designing and implementing loans, the impression one gets is that most officers are eminently competent, have ample experience in what they are doing and mean well. Perhaps idealism is too strong a word, but very few officers are cynical or jaded about their work. They try to get to know the aspect of the country they are dealing with and produce competent analysis, leading to the policy lines they think would be most appropriate. Of course, they have made many mistakes along the way. But they are doing their best and nobody really knows how to promote the development of a country. It was an easy bet to rebuild factories or roads in Germany. But what should they do in Chad or Haiti?

A most relevant aspect of their work has to do with new ideas for reforming policies and institutions. No other agency in the world has generated so many innovations in these matters, most of the time, backed by solid empirical research. In fact, no other agency has several thousands well-trained professionals in their staff, with ample experience in the field.

Long gone are the days when UNESCO had a leading role in spearheading new ideas in education. The WB has taken up this role in earnest. It is instructive to remember that the Jomtiem meeting of Education for All had the strong leadership of the WB. UNESCO had no choice but to participate, without having a strong voice in the ideas and organization.

In education alone, the banks have championed the use of student's evaluations, carefully prepared textbooks, accountability of programs and agencies, merit pay for teachers, competitive bids for training contracts, new schemes for vocational schools, student loans, vouchers, and many other policies.

It is instructive to notice that some of these ideas were initially rejected with vehemence but, after so many years, became acceptable practices. A case in point is students' evaluation that is increasingly considered as the best tool to monitor education.

The main problem is that the speed of acceptance of new ideas often does not coincide with the life cycle of a loan. It may take much longer for an idea to be accepted. Loans are bureaucratic procedures with timetables and budgets. Ideas have a life of their own, float around, and may find strong rejection for a much longer time than the loan lasts.

Policy and ideological issues have become the object of live discussion and sometimes bitter arguments by outside critics. Yet, it is the contention of this paper that most of these invectives miss the point.

The Achilles' heel of the entire lending process is not ideology or imperialism. The real issue is whether the loans deliver what they are supposed to deliver, ultimately, development. As suggested before, implementation is a big problem. Banks staff and rules are a lot less enlightened in delivery than in conception. Bank procedures to execute a loan are ponderous and inflexible.

Worse, there are no powerful forces to seriously repair projects that do not seem to be performing well. There are no prizes for whistle-blowing. In fact, along the chain of design and execution, everybody may be guilty of some error if the project does not perform. For that reason alone, there is a strong reluctance to denounce poor performance and to redress procedures. For almost all concerned, hiding weaknesses may be a more expedite line of action. This is also true for the Ministry that receives the loan. It is highly probable that its performance has been less than stellar in managing it. The last thing it wants to do is to recognize those failures and do something about them.

Loans get delayed, disbursement stalls for bureaucratic snags, and abrupt changes in staff create havoc with execution. And above all, those reform components that happen to carry a greater political price fall behind and may never be implemented.

That is not to say that all or most of the loans are ultimately ineffective. This is not the case. However, despite the effort of evaluation offices, we know little about their impact on development.

The New Scenarios

The world is changing, perhaps faster than one would expect or like. The situation of multilateral banks is presently quite different from what it was 10 years ago.

Many of the implementation problems presented in this essay reflect recurring issues facing the banks. However, while most of these problems have not been solved, new ones emerge.

Banks have no problems to raise capital. All they need is to float titles in the world's financial markets. However, potential borrowers are increasingly less interested in taking loans.

In the 1990s, many countries were having difficulties in continuing to take loans from development banks. Several were indebted beyond the agreed limits of the IMF. They just could not borrow more.

In more recent years, surfaced another equally serious problem for the banks. It has to do with the better creditworthiness of some countries (in Latin America, Brazil, Chile, and Mexico are classical cases) and the huge amount of private capital migrating to "emerging markets." The implications are clear. Countries now can borrow from the private banking system at favorable interest rates. And with private banks, the hassle of preparing a loan and executing the project is drastically reduced. Private banks do not ask many questions on how the funds will be spent. Once satisfied that the client will pay back, the rest is not their problem. Therefore, some of the operations that previously were going through multilateral banks are diverted to private banks.

This has been a major setback for the multilateral banks and matters may become worse in the future. In Latin America, the largest countries, borrowing the bulk of the

available funds, have slowed down and reduced their business with the WB and the IDB. In smaller countries, even when they are permitted to borrow, the total of their operations amounts to a small proportion of the funds set aside for lending. In addition, the fixed costs of preparing a loan hardly justify the amount borrowed.

In the last several years, both the WB and the IDB have initiated programs to lend to the private sector of their client countries. These operations are growing and this is an area in which considerable expansion may be possible.

However, it does not seem reasonable to think that they can expand to the point where they make up for the loss of business resulting from the limitations imposed on countries to borrow more. After all, the same abundance of private credit makes the multilateral banks less competitive, given their ponderous and time-consuming bureaucratic procedures.

Perhaps the most promising responses by the bank, in order to face these new and difficult predicaments, lie in the development of new financial products. While both banks always had a variety of modes of lending, the conventional loans to fund a well spelled-out set of projects always predominated.

The new trend is to expand loans under which the country agrees on a broad set of objectives and receives a lump sum of money to pursue them. These are outcome-based loans. Since countries freely choose the project, they thereby acquire greater "ownership."

But there are also variations on the conventional loans. An interesting alternative is to negotiate a step by step loan. Instead of making a loan and repeating the entire bureaucratic rites for the next one, along the same lines, there is an agreement that once the first is successfully completed, it can lead almost automatically to the next.

All things considered, multilateral banks are not in a comfortable position. Living in a buyers' market is far more difficult. For a long time, countries could not change fast enough to satisfy their goals of reform. Now the world seems to be changing too fast for them to catch up.

Notes

1. The author is presently the President of the Advisory Board of the Pitágoras System, but he has been a regular staff member of the World Bank and the Inter-American Development Bank. My gratitude to Ricardo Santiago, also a former IDB officer who read the manuscript and made useful suggestions. However, he does not necessarily endorse all ideas presented here.
2. While other multilateral banks are similar, the author is not familiar with them.
3. Some of the sources come from internal memoranda and other papers that were not meant to be published.
4. To simplify the discussion, this chapter ignores what are called IDA operations, geared to the poorest countries in the regions. These loans use money directly provided by donor countries. In these loans, the countries providing the capital have a much stronger voice.

TOWARDS THE EUROPEAN PANOPTICON: EU DISCOURSES AND POLICIES IN EDUCATION AND TRAINING 1992–2007

George Pasiás and Yannis Roussakis

Introduction

The 1990s were marked by various challenges, changes and transformations at the economic, geopolitical, social and technological levels (Held & McGrew, 2000; Adam, Beck & van Loon 2000; Reich, 1991) which, in several instances, affected the ongoing transformation processes of the European Union (EU). These challenges were often related to factors such as the globalisation of the economy, the growth of Information and Communication Technologies (ICTs), the rapid development of ‘techno-science’ and the immigration influx to Europe. At the economic level in particular, changes were dominated by the widespread effects of the new technologies in the industries and the enterprises, and by international agreements for the liberalisation of markets and trade (e.g. the World Trade Organisation General Agreement on Trade in Services – WTO/GATS), which changed both the relative significance of the production factors and the international division of labour (Aglietta, 1998). The perceived challenges of this new economic order were underlined in the new ‘human and social capital’ theory (Baron et al., 2000), which argued for a new, knowledge-based distribution of labour, flexible production forms and relationships, high specialisation, performativity and mobility of the workforce (Lyotard, 1984; Burton-Jones, 1999; Hargreaves, 2003). In the early 1990s, the structural and social consequences of these economic and technological changes were acknowledged at the EU level, with special reference to the ‘technological/competition gap’, the ‘regional inequalities’ between the member states, the ‘demographic problem’ and ‘unemployment’ and ‘social exclusion’ in the European societies (Maravegias & Tsinisizelis, 1995). These transformations accelerated the decisions concerning the institutional, political and economic status-quo of the European Union, and they led to changes in the economic dimension (e.g. the establishment of the EMU and the Euro zone, 2001), in the geopolitical dimension (e.g. the enlargement with the Eastern and Central European countries in 2004), in the political dimension (e.g. the process for establishing a EU Constitutional Treaty between 2004 and 2006) and in the social dimension (e.g. accounts of demographic ageing, modernisation of pension systems and employment).

All these developments gave new meaning to significant concepts like European Union, European citizen, economic and social cohesion, European governance, and

introduced new discourses on competitiveness, quality, employability, performativity, convergence, which permeated the EU politics and policies (Bonal 2003; Marglhaes & Soter, 2003; Pasias, 2006b: 63–70). They also constructed a new operational context for education, which gradually became a high-priority area in the Community's politics and policies. Education and training were directly linked with the central EU policy choices in the fields of the economy, social cohesion, scientific research and innovation, which, in the words of the Lisbon Strategy, aimed at 'Europe to become the most competitive knowledge economy in the world' (European Council, 2000a). At the same time, education became a part of political actions aiming at the enhancement of the symbolic and 'imagined' content of European integration (e.g. European governance, European citizenship, European identity), and the transition to the 'knowledge societies and economies' and the constitution of a European polity.

In the Sorbonne Declaration (1999), the document which had set the ground for the 'Bologna process' in European higher education, the Ministers of Education of France, Germany, Italy and the UK, four of the core members of the European Union, stated that:

The European process has very recently moved some extremely important steps ahead. Relevant as they are, they should not make one forget that Europe is not only that of the Euro, of the banks and the economy: it must be a Europe of knowledge as well. We must strengthen and build upon the intellectual, cultural, social and technical dimensions of our continent. (Sorbonne Declaration, 1999: 1)

The concept 'Europe of Knowledge' in its current EU meaning emerged in the 1990s to describe the radical changes that took place in the field of 'knowledge' and to categorise contemporary societies and post-industrial economies which are considered to be knowledge-based and informational, open, innovative and communicative (Stehr, 1994; Delanty, 2001; Stone, 2000; Castells, 1998). As an approach to education, 'Europe of Knowledge' is sometimes considered as a signifier of a certain socio-economic, political, cultural and educational 'paradigm', identified with a certain construction of the European educational reality. In this sense, the way 'Europe of Knowledge' is presented by the EU actually serves as a 'roadmap' or a 'diagram' of 'power-knowledge' relations in the European Union, exemplifying the close nexus of discourses and practices that aim at the formation of a European Area of Education.

The purpose of this chapter is to examine critically the educational discourses and policies of the European Union since its institutionalisation with the Treaty of Maastricht in 1992, and their constructed concept of a 'Europe of Knowledge'. It will be argued that the educational policies of the EU are strongly related to its political and economic goals, and that they are often enjoined to serve these goals in a passive and uncritical manner. It will be argued that the educational discourses and practices of the Union are often used as, what M. Foucault would call, 'regimes of truth' (Foucault, 1980: 133). They indicate acceptable systems of knowledge, which are in turn used for knowledge politics control and the legitimisation of educational reforms, at both the national and the European levels. It will also be argued that the educational politics and policies of the EU are dominated by the interrelated discourses of marketisation, regulation, competitiveness and performativity, which draw from and are influenced by the ideology of 'technocracy', and by the ideas and

practices put forward by certain economically oriented international organisations such as the OECD, the World Bank and the IMF. Finally, it will be argued that the rhetoric of ‘quality’, ‘sustainability’, ‘employability’, ‘competitiveness’, ‘accountability’, ‘economic and social cohesion’, used by the EU in its Europe of Knowledge educational discourses and practices, is actually a form of ‘governmentality’. As such, it could be argued that the EU is dictating, in a covert or overt manner, politics of ‘surveillance’ and ‘control’ of national education policies and planning, literally establishing a contemporary ‘Panopticon’ of the European Education Area.

Education in the EU after Maastricht

Education and training were institutionalised as ‘competences’ of the European Community for the first time in the Treaty of Maastricht (Treaty of the European Union/TEU, European Council 1993). The relevant articles were based on the principle of subsidiarity, which delegated the division of power over education and training to the member states and the European Union. The phrasing of the text indicated that there was a clear differentiation of the scope and the aims of Community action between education, where the Community ‘contributes to the development of quality education’ (Article 126), and training, where the Community ‘implements a vocational training policy’ (Article 127). The two policy areas were further differentiated with respect to the decision-making processes which prevailed for each one of them. For education, decision-making usually followed the procedures of Article 189B (the co-decision procedure), while training issues were decided following mostly the procedures of Article 189C (the cooperation procedure). The institutionalisation of education in the TEU also entailed the upgrading of the administrative structures responsible for education and training in the European Commission, leading to the establishment of a General Directorate in 1995.

In examining the involvement of the EU in education and training since 1992, we can distinguish three different periods, which are marked by different perceptions of the role of education and training in the Union and the predominance of different discourses and policy practices. These periods are: 1993 to 1996, 1997 to 1999 and 2000 to date.

The Policy Consolidation Period, 1993–1996

The first period, which is characterised by the Commission’s attempt to consolidate education in the Community apparatus, extends from 1993 to 1996. This period was characterised by intensive debate and activity which resulted in important changes in the ways education, as discourses and practices, was perceived in the EU context. It also resulted in the expansion of the indirect and implied competences of the Community towards education. Concurrently, a wider legalisation procedure was launched which aimed at strengthening the complementarity of education and training to other policy areas of the Community (especially to in the social, the technological and the cultural domains).

Education was perceived to be an important element of a wider strategy, which aimed at the consolidation of the EU as a political and economic entity and a world player, but also as an ‘imagined community’, in Benedict Anderson’s meaning (Anderson, 1983).

This second task seemed urgent at the time, considering the difficulties encountered during the ratification process of the Maastricht Treaty. The reactions of the European electorate emphatically showed that the European integration project needed ideological and symbolic depth within the national civil societies. In order to respond to those voices which argued that the EU perspective was irrelevant or hostile to the European societies, the European Commission circulated several policy documents that referred to issues with a visible impact on concerned Europeans. Such issues included 'social solidarity' (EC, 23-12-1992), 'social policy' (EC, 17-11-1993), 'citizenship' (EC, 21-12-1993), 'democratic deficit' (EC, 5-5-1993) and 'transparency' (EC, 2-6-1993) of the EU governance. All these documents and the policies which they initiated, served, in one way or another, the attempt to enhance the symbolic, imagined and ideological meaning of European integration and to coin expressions such as 'European home', 'Europe of citizens', 'European governance' and 'diminution of democratic deficit'.

In order to take advantage of education as a 'Europeanisation' factor and to pinpoint the huge European intellectual and human potential as a 'competitive advantage' in its struggle against international rivals (such as the USA and Japan), the EU had to consolidate education and training in the Community edifice as soon as it would be able to do so. So, in a very short time, it attempted to construct a discourse that would bring about a significant change in the perception of the role of education in Europe. The institutional framework of education in the Maastricht Treaty made this attempt easier than ever before in the history of the Community. In the 1980s, particularly during the 1986–1992 period, the European Commission used the political and economic goals of the Community (e.g. European unification, the common market and the emergence of European citizenship), to justify its involvement in education through action programmes, and to legitimise the educational initiatives put forth at the European level (Pollack, 2000: 520). After Maastricht, the educational objectives were used in order to support and enhance the political, economic and social goals of the EU (e.g. convergence, adaptation, interaction and cohesion). By the late 1990s, a radically different perception of the role of education, at the discourse level, had taken shape, mainly in the context of the European Strategy for the Employment and Social Cohesion. Education, which was formerly perceived by many European governments to be part of the crisis of the welfare systems, had gradually been transformed to perhaps the most significant institutional factor which would help Europeans to resolve this crisis (Pasias, 2006a: 373–374).

In the 'Guidelines for education in the '90s' (European Commission, 1993c), a document which summed up the Commission's initiatives, we see clearly that the European Commission had developed its educational discourse through commonly agreed significant documents (mainly Green and White Papers). These documents were powerful instruments of political intervention both at the European level – through the support provided to cooperation networks among educational organisations, the labour market and social partners – and at the national level by affecting national educational planning and reforms. The discourse which emerged from these documents linked education and training policies with the EU policies for competitiveness, employment and social cohesion.

In the White Paper 'Growth, Competitiveness, Employment: The Challenges and Ways Forward into the 21st Century' (1993), which described and analysed the

perceived challenges for the European Union in a changing international environment, it was argued that:

The Community should set firmly and clearly the essential requirements and the long-term objectives for measures and policies [in education and training] in order to make it easier to develop a new model for growth, competitiveness and employment in which education and training play a key role and to ensure essential equality of opportunity and the coherent development of the three dimensions of the European system of education and training (education, training and culture). (European Commission, 1993a: 122)

It was also proposed that this should be done by ‘developing, generalising and systematising lifelong learning and continuing training’. According to this White Paper, this meant that ‘education and training systems must be reworked in order to take account of the need which is already growing and is set to grow even more in the future’ (European Commission, 1993a: 120).

The same principles were further elaborated in the Commission’s White Paper ‘Teaching and Learning - Towards the Learning Society’ (1995). This Paper attempted to identify the role of education in an emerging European Knowledge Society and Knowledge Economy in the light of three presumed ‘factors of upheaval’, namely ‘globalisation’, ‘information society’ and ‘techno-science’. It also attempted to mark out a strategy for the development of human resources in view of the EU’s transformation of the European ‘Knowledge Society’. Right from the start it argued that ‘investment in knowledge plays an essential role in employment, competitiveness and social cohesion’, and that ‘the individual’s place in relation to their fellow citizens will increasingly be determined by their capacity to learn and master fundamental knowledge’ (European Commission, 1995b: 1–2).

In both these texts the Commission actually constructs a ‘market orientated discourse’ for education. It has been argued that this discourse draws from, and aligns with, the neoliberal perceptions of international economic organisations such as the OECD, the World Bank, and the International Monetary Fund, as they foreshadow the future development of education and training systems in the post-industrial societies (Kazamias, 1995; Field, 1998; Spring, 1998). In order to identify the labour market relationships and the employment conditions of the future ‘knowledge societies and economies’, the aforementioned White Paper coined a number of key-concepts such as: ‘competitiveness’, ‘adaptability’, ‘elasticity’, ‘flexibility’, ‘quality’, ‘certification’ and ‘evaluation’. It also advocated policies which primarily aimed at the development of flexible skills and competences, at the expansion of access to continuous training, at the certification of formal and informal qualifications and at the closer relationship between educational institutions and business enterprises (European Commission, 1995b: 44–47). On another widely debated issue, that of the financing of education, the White Paper questioned the view that education is a public good and advocated the reduction of public spending and the promotion of co-financing or self-financing processes by education and training recipients (European Commission, 1995b: 48). The influence of the market discourse on the White Paper is further underlined in its

proposals to establish an outcomes-oriented system of evaluation of education based on measurable criteria (e.g. quality, productivity, performativity and effectiveness) and to finance education and training systems based on results (European Commission, 1995b: 46–49). In this sense the educational project presented in these White Papers, leads to a circumscribed perception of the ‘Europe of knowledge’ dominated by the neoliberal views about the world economy.

In an attempt to counterbalance this ‘economistic’ view of education, the Commission, in both documents discussed above, but also in the Green Paper on the ‘European dimension in education’, included some references to the cultural tradition of the European education systems. In the Green Paper, the Commission pointed out the need for the adaptation of the educational process to the new economic, social and cultural context of a unified Europe, which aimed, among other things, at the construction of a European identity, the improvement of the quality of education, the preparation of young people for better social and professional integration, and the further promotion of cooperation among educational institutions in the member states (European Commission, 1993a: 9–13).

The EU educational discourse during this period was further elaborated in three consultation documents: the Green Papers on ‘Innovation’, ‘Life and Work in the Information Society’ and ‘Obstacles of Mobility’. In these texts the Commission: (a) pointed out that one of the obstacles to innovation was ‘the insufficient adaptation of education and training systems to the reality of a changing world as well as the great lack of flexibility of structures and their rules of development’ (European Commission, 1995a: 36–37), and (b) proposed a radical restructuring of education and professional training systems which would incorporate the ICTs for their future development since ‘the basic need for Europe is to develop a new architecture via lifelong learning and professional training’ (European Commission, 1996a: 26). Mobility was then considered to be an answer both ‘to the economic challenges via the internal market formation processes and to the social implications, particularly to employment matters’ (European Commission, 1996b: 1).

Education in the Shadow of the Structural and Employment Policies, 1997–1999

The second period of the EU’s involvement in education extends from 1997 to 1999. During this period, education was directly linked to the Community’s structural and employment policies which aimed at supporting the readjustment of the relevant policies of the member states and the modernisation of the education, training and employment systems. The new Structural Funds Regulation (1999) as well as the European Strategy for Employment (1997–1999) were built, according to the Luxemburg European Council Conclusions on four distinctive policy pillars, namely ‘employability’, ‘entrepreneurship’, ‘adaptability’ and ‘equal opportunities’ (European Council, 1997).

The new cartography of the EU education policy also included the construction of two specific educational ‘policy networks’:

- (a) An 'official'/'formal' network, which drew upon and was supported by Articles 126 and 127 of the TEU and was framed by the EU Council Decisions and Directives. This network included the Community action programmes (SOCRATES, LEONARDO and TEMPUS) as well as the mechanisms for the mutual recognition of qualifications (ECTS, Europass and EQF). It was financed by the new DG 22 of the Commission and it operated according to the Community method. Its central goals were cooperation, mobility, exchanges and recognition of qualifications, aiming at integrating initial and further education systems.
- (b) An 'informal' educational network, which drew upon other competences of the EU (such as employment, mobility and social cohesion) and was linked to other policy areas (e.g. structural, employment, social, research and culture). It was framed by the Decisions of the European Council, which regulated the EU structural policies, the European Strategy for Employment and the Lisbon Strategy, and was intended to control national educational planning. It was implemented via both the Community method (through the Structural Funds Regulations) and an early form of the Open Method of Coordination (OMC). This method aimed at economic convergence and social cohesion in the member states, which was also reflected in the pursuit of 'commonly agreed' educational objectives. The national action plans for employment and education, which were subsidised by Community resources made available to the member states through the Community Support Frameworks (also known as Delors I, Delors II and Santer packages) are a genuine example of this approach (Addison & Siebert, 1994; Christodoulakis & Kalyvitis, 2004).

In the late 1990s, the major EU educational policies were characterised as follows:

- (a) By the predominance of an economic-technocratic-instrumentalist perception which was connected with and controlled by the emergence of new 'discourses', the imposition of new 'regimes of truth' and a new mode of setting and implementing 'regulatory processes' such as globalisation, marketisation, risk society, ICT society, governmentality and performativity (Pasiás, 2006a; Kazamias & Roussakis, 2007).
- (b) By the prioritisation of the development of a 'new competence framework', consisting of professional and social competences, which was based on a 'new human and social capital theory'. The new competences aimed at the adaptation of the European workforce to the requirements of the job market and the new knowledge based distribution of labour, and at the reduction of the obstacles of intra-EU mobility (European Commission, 2005b, d)
- (c) By their emphasis on a 'high-quality general education', on the enhancement of innovative lifelong learning structures and on the development of horizontal competences, such as 'learning to learn', 'cultural awareness', 'foreign languages' and 'entrepreneurship', which were then considered as inevitable requirements for the incorporation and the growth of enterprises (European Commission, 2001, 2005d).

These features clearly marked a shift in the EU discourse on education, which was now seen as an instrument to achieve the political goals of the Union. This shift to the 'politics of knowledge' was discussed for the first time in Agenda 2000 (European Commission, 1997a). In this text the Commission argued that the globalisation of the economy and the information and communication technologies favoured the emergence, the growth, the dissemination and the utilisation of new 'immaterial goods', which affected the EU economic enlargement, competitiveness and employment. To the extent that 'technological research, education and training constitute essential immaterial investments, the "politics of knowledge" (innovation, research, education and training) have decisive consequences for the future of Europe' (European Commission, 1997a:12–13).

The 'politics of knowledge' were further elaborated in 'Towards a Europe of Knowledge' (European Commission, 1997b). Here the European Commission presented in a comprehensive way the Union perspective for education, namely the functional framework, the perceived significant factors, the dimensions that should be developed and the objectives that should be pursued. The Commission argued that the Community politics for education 'are inspired by a fundamental orientation: the progressive creation of an open and dynamic European educational space, in which the principles of lifelong learning education and training will be implemented'. The Commission also underlined that the challenges for the formation of the European educational space presupposed 'the unification of sectors of education and training' and required the rationalisation of the educational policies of the member states through 'the economy of the intentional objectives', the 'restriction of measures and the dissemination of actions', and the establishment of a 'framework of common purviews between the Community, the member states and the other involved agents' (European Commission, 1997b: 5–7).

The wider perspective of the Europe of knowledge, which encompassed most of the Community discourses and practices for the economy and employment, is schematically presented in Table 1. The politics of knowledge in this document have been fundamental to the central policy talk and policy practices which have dominated the post-1997 period. It can be argued that they constitute the matrix of the objectives, the practices and the technologies occupied by the Lisbon Strategy, which was adopted in 2000 and is discussed in the next section.

From the texts discussed above, it appears that the educational policy of the EU was constructed on the basis of the key-conceptual axes of 'convergence', 'cooperation', 'cohesion' and 'prospect'. By the late as the 1990s, both the Commission and the member states had accepted the view that the possibilities of a wider educational cooperation that aimed at convergence/cohesion in education and training were limited, while strictly following the 'action program-approach'.

The Commission was heavily criticised for 'ineffective administration' of the action programmes and for 'disproportionate bureaucracy' (Ertl, 2006:14). It was also obvious at the EU level, that owing to the institutional barriers imposed by the principle of subsidiarity it would be impossible for the Commission to advocate or promote interventionist policies in the educational reforms of the member states that aimed at the convergence and the European modernisation/Europeanisation of the national educational systems. There were strong views (see for example, Berggreen-Merkel, 1999: 3–4) that the medium-term and long-term perspectives of educational cooperation

Table 1. Europe of knowledge and the educational *Panopticon*

European Educational Space	<i>The 3 basic dimensions</i> Knowledge Citizen Employment
Knowledge	<i>The 4 basic areas</i> Innovation Research Education Training
European Knowledge Society	<i>The 5 main axes/objectives</i> (a) To develop lifelong learning and continuous training (b) To maintain the social model in the European Union (c) To preserve European identity (d) To decrease the social gap (e) To increase employability
European Knowledge-Based Economy	<i>Keywords used to describe the education – employment Relationship</i> Innovation Competitiveness Compliance Employability Flexibility Adaptability Quality Evaluation Certification Performativity Effectiveness Expendability
The politics of Knowledge	Instrumental rationality technocratic discourse Legalised reframing scientific legitimisation Voluntary participation cooperation cohesiveness
The Lisbon Strategy for Education	<i>The concrete future objectives</i> Quality Accessibility Openness (via lifelong learning processes)
The educational Panopticon	<i>The technologies of knowledge</i> Participation, representation, consultation, theasis, mutual learning, governing, management, monitoring, evaluation, accountability, control, performativity, surveillance <i>The continuous evaluation and surveillance</i> OMC, benchmarking, custody rules, standards, indicators, criteria, strict timetables, monitoring, mutual learning, exchange of best practices, peer review

clearly demanded new working procedures in agenda setting and in the operation of the EU, e.g. the EU Education Council. In this context, the initiative for the Council resolution on the ‘Rolling Agenda’ (1999) was received as a clear step towards ensuring a greater continuity and enabling a more effective exchange of information, experience and good practices between the member states (Hingel, 2001:9).

Discourses and Policies of Education for the New Millennium, 2000 Until Now

In the light of the challenges of economic globalisation and the geopolitical transformations at the international level after September 11, 2001, the European integration process acquired particular interest at the pragmatic level (e.g. the economic and social) and at the symbolic/imagined levels, pertaining to the role and the status of the European Union in the new world order. The establishment of the European Monetary

Union (EMU), the enlargement towards Eastern and Central European countries and the ambitious project towards the establishment of a Constitutional Treaty, all contributed to a further conceptualisation of the EU as a single, *sui generis* comprehensive geopolitical totality with members sharing common goals and views for the future. As a consequence, with the new millennium, both the context and the content of the EU politics and policies became more complex and were radically reconstructed.

In the early 2000s, both the member states and the Commission decided that further steps towards a cohesive European educational policy were needed, which, still under the principle of subsidiarity would promote convergence of educational systems and the making of a European education area of lifelong learning. This perspective was deeply influenced, among others, by (a) the effects of the European Monetary Union (EMU) and the introduction of a common currency in the Euro zone, (b) the commonly agreed European strategy for employment, (c) the perceived competences needed for the knowledge society, and (d) the developments towards a more open and transparent European governance that gave meaning to the European citizenship. In this renewed process of the ‘unionisation’/Europeanisation of education and training, the main goals put forward by the Commission since the late 1990s, summarised in the views that the EU expressed towards knowledge, competitiveness and employment have been directly linked to distinctive EU policies, processes and strategies.

In the years after 2000, the division between the Commission’s official/formal action programmes and the informal national action plans, as well as the Commission’s educational politics and policies have been acute. The initiatives of the member states, through an extensive agenda of intergovernmental activities and agreements, have been decisive for the planning of future educational policies. Such activities and agreements have included the Lisbon process that aimed mostly at general education, the Copenhagen process that dealt with vocational education and training and the Bologna process, which aimed at the construction of a European Area of Higher Education. The first two drew immediately from the Lisbon Summit Conclusions (European Council 2000a), while the Bologna Process began as an independent intergovernmental initiative in which the Commission although sceptical at first, chose to take an active part. All these processes deployed some form of the Open Method of Coordination (OMC), which, as we elaborate below, has been a major breakthrough in the way education and training are steered by the Union. The most distinctive initiatives affecting education and training, which derived from these processes, included the following:

- (a) The contribution of education and training to the formation of the “European labour market, open to all, with access to all” (European Commission, 2001) and to the European strategy for employment and the growth of the knowledge economy (European Commission, 1997b). The EU supported this development through life long learning, education and training policies, such as the Action Plan for skills and mobility 2002–2004 and the “Lifelong Learning Programme” (2007–2013).
- (b) The modernisation and the quality improvement of all levels of education and training, in consonance with policies aiming at innovation and competitiveness in the information society. This initiative involved the promotion of

convergence and a more centralised control of national educational planning, as advocated by the Programme “Education and Training 2010” (Council of the EC, 2002, 2003).

- (c) The construction of the European Higher Educational Area, which would facilitate, on the one hand, the mobility of students, researchers, academics and education services, and on the other, the mutual recognition of qualifications and periods of study.
- (d) The formation of the European vocational education and training area promoted by the “European Competences Passport” (Europass), the European certification of qualifications (EQF) and the European recognition of periods of study.
- (e) The strengthening of a European identity, of European citizenship and of social cohesion, in tandem with the objectives of accessibility, openness and equality of opportunities that aimed at the maintenance of a distinctive European social model (European Council, 2002).

Since the late 1990s, it has been obvious that lifelong learning gradually has become the central concept and the strategic objective of education and training policies towards the knowledge based societies (European Council, 2000a, 2000: 1). The Commission emphasised that ‘the enormous economic and social changes that happen in Europe require a completely different approach of education and training, ... which must be faced off by a framework of lifelong learning, ... which will be directly linked to youth, employment, social inclusion and active participation in society’ (European Commission, 2001: 3).

Although the Commission recognised the limitations of the ‘action programme approach’, it renewed the implementation of SOCRATES, LEONARDO and TEMPUS, and initiatives such as ‘e-learning’ and ‘skills and mobility’. The Commission reframed this approach by introducing the new integrated Lifelong Learning Programme (2007–2013). At the same time, it emphasised ‘education and training 2010’, which stemmed directly from the Lisbon strategy. Moreover, the role and the status of the Commission continued to grow stronger in two areas: (a) in the discourse/policy talk formation (e.g. ‘Europe of knowledge’, ‘European governance’, and ‘active citizen’), and (b) in the policy practices implemented through the European strategy for employment and the distributive policies of the Structural Funds (Pasias, 2006b: 91–94).

The Lisbon Process for Education and the Open Method of Coordination

The Lisbon Process for education, the Copenhagen Process for vocational education and training and the Bologna Process for higher education, are the constituent elements of the discourse that constructs, deconstructs and reconstructs the European educational landscape. Placed conveniently within the rhetoric of lifelong learning, European Knowledge Society and Knowledge Economy, these processes initiate and demand innovative and radical challenges, at both the EU and the member states levels, of decision-making processes and policy choices for education and training. They challenge the long established ‘Community approach’, which operates through the

implementation of the Community initiatives, programmes and action plans, in favour of a 'common interest/common goals' approach. This 'common goals' approach is essentially a 'steering by results' approach to education and training which requires and leads to wider changes both at the discursive and the political/administrative levels.

The 'Europe of knowledge' as perceived through this new educational 'canon', corresponds with a specific construction of European reality which is directly linked to 'technocratic' claims in education. These claims are articulated in such key-concepts such as 'new knowledge', 'new skills' and 'new competences', which describe the requirements of knowledge-based economies and societies (OECD, 2000; European Commission, 2005b, d). In this sense, the formation of a European educational area is closely connected with the emergence and dominance of a new political-technocratic elite of educational 'eurocrats', which is comprised of groups of 'experts' (technocrats-bureaucrats-administrators) both at the national and the EU levels. This elite acts and makes decisions that are based more on technocratic criteria than on democratic ones (Radaelli, 1999).

In the Lisbon Summit, the first European Council summit of the new millennium, the European leaders attempted to respond to the challenges posed for the Union by the contemporary global discourse. Specifically, these challenges included: (a) the external challenges, such as globalisation and marketisation, (b) the future steps in the process of 'unionisation/Europeanisation' (enlargement, convergence, integration and unification), and (c) the major concerns of the member states towards needed reforms.

As we have already mentioned, the strategic overarching goal for the European Union as was articulated in the text of the Lisbon Summit Conclusions, was 'to become ... the most competitive and dynamic knowledge-based economy in the world'. Towards this end, the Open Method of Coordination (OMC) was adopted as a process of policy choice and implementation and as a 'means of spreading best practices and achieving greater convergence towards the main EU goals'. Among other things, the OMC allows the Commission:

- (a) To coordinate intergovernmental bodies in the process of setting European guidelines and translating them into national and regional policies
- (b) To set specific measurable targets towards the commonly agreed objectives
- (c) To adopt measures and timetables of implementation, using indicators and benchmarks for the comparison of its performance with non-European global competitors
- (d) To evaluate the progress through periodic monitoring and peer review

The Lisbon Process for education initiated a number of changes in the educational policy of the EU. These included the following:

- (a) A shift from the European Commission's 'action programme approach', to the Council's 'competence-based model'. This new approach prioritised short and mid-term commonly agreed objectives, and entailed the continuous assessment of the educational initiatives of the EU with the use of indicators and benchmarks
- (b) Downplay of the 'Community method' of co-decision and, concomitantly, of the subsidiarity principle for Community involvement in education, in favour of the open-ended and voluntary open method of coordination

- (c) The gradual abandonment of the dogma of ‘non-harmonisation’ of the education systems member states, in favour of a more ‘Europeanised’ control of the national education planning and policy choice

These changes in the views of the EU towards education can be seen as a result of a wider shift of the policy process in the EU. After 2000 the EU gradually moved from the neutral/defensive intergovernmentalism of the 1990s, which prioritised the subsidiarity control of the scope of the EU activities, to two radically different directions. It adopted an emphatic/aggressive intergovernmentalism, which entailed the voluntary commitment of the member states, and a resurrected notion of ‘neofunctionalism’, which advocated the spillover effect from education to the economy and employment.

The changes mentioned above can be clearly read in the mandate of the Lisbon European Council to the Education Council of the EU, ‘to undertake a general reflection on concrete future objectives of education systems, focusing on common concerns and priorities while respecting national diversity’. One year after the Lisbon Council, the Education Council identified three strategic objectives identified for the European education and training systems:

- ‘Increasing quality and effectiveness of education and training systems in the European Union’
- ‘Facilitating the access of all to the education and training systems’
- ‘Opening up education and training systems to the wider world’ (Council of the EU, 2001: 7)

These three strategic objectives became the basis for the establishment in 2002 of the ‘Education and Training 2010 Programme’ as the single comprehensive framework for cooperation in the field of education and training. The Programme transcribed the three objectives into specific policy areas that would be closely monitored and reviewed by specialised working groups which would use a defined set of indicators and benchmarks (European Commission, 2003a).

Six years after the launching of the Lisbon strategy, the findings of research as well as the official progress reports indicate that the effects of the Lisbon process for education appeared to be ‘more rhetoric than real’ (Ertl, 2006: 22). It was found that there were serious inequalities in the achievement of the commonly agreed objectives among the older European core member states, e.g. England, France and Germany, the southern European region (Greece, Spain and Portugal) and the new EU members states of central and eastern Europe (Ertl & Phillips, 2006; European Commission, 2005a). In their reports, the Commission and the Council attributed these drawbacks to the vagueness of the Lisbon objectives, arguing that they covered vast policy areas which were poorly coordinated and without clearly stated priorities (European Commission, 2003b,c). They recognised that the Open Method of Coordination did not bring about the expected results, since it depended too much on the willingness or the ability of the member states to compromise the objectives for European convergence with their national particularities. Scholars of education policy, on the other hand, have argued that the main reason for the observed disparities and the non-achievement of the Lisbon objectives is the diversity in the historical national contexts of education. Community directives, initiatives and action plans, concerning the implementation of

both the Lisbon and the Copenhagen Processes, are interpreted and implemented in different and often divergent ways by the various member states (Ertl & Phillips, 2006: 86; European Commission, 2005c).

Even though there are clearly identifiable drawbacks in the Lisbon Process, the fact remains that, through the Lisbon strategy, the Community policy discourses and practices have operated as mechanisms of control of educational policies of the member states. The aim of this process was to achieve convergence of education and training systems via a mechanism of continuous monitoring, measurement and surveillance (Hodson & Maher, 2001; Hostens, 2003; Pasias, 2005). As several scholars have argued, this approach coincides with the discourse on control, evaluation and performativity of education and training systems, emanating from international organisations such as the World Bank, the OECD and the International Monetary Fund (Spring, 1998; Borg & Mayo, 2005; Ball, 2003; Ilon, 2002). This discourse uses terms such as competitiveness, productivity, adaptability, flexibility, employability, trainability, effectiveness and accessibility to describe the basic main characteristics that modern educational systems must possess in order to adapt to the globalised, competitive and changing economic environment (OECD/CERI, 1994). It also advocates processes such as control, monitoring, accountability, total quality control, standards, indicators and benchmarks, to describe the basic instruments which education systems must use, to adapt to the demands of the knowledge-based economies (OECD, 2002). This approach significantly changes the nature of knowledge pursued by education and training systems. It emphasises and prioritises outcomes, learning products and qualifications. Acceptable knowledge is the useful, measurable knowledge. In the context of a technocratic knowledge-based economy, knowledge is a commercial commodity-product which can become 'consumable' and constantly renewable. The whole argument of lifelong learning is based on the assumption that knowledge is 'consumable'. In the context of lifelong learning, however, it is not only knowledge itself that is 'consumable', but also the object of knowledge as well as the subject of knowledge, both individual and collective.

In this context, OMC, a process directly drawn from the evaluation procedures of multinational companies for education (Arrowsmith et al., 2004), creates the need to produce 'technologies of surveillance' as tools for the measurement of progress towards certain defined objectives, e.g. (a) to invent 'technologies of performance' as tools for the exchange of best practices; (b) to introduce 'technologies of *theasis*' (gazing) as tools for imprinting and depicting outcomes such as indicators, tables, graphics and statistics; and (c) to utilise 'technologies of governance' as tools of mutual learning which may provoke political dialogue (Haahr, 2004; Nóvoa & Yariv-Mashal, 2003; Pasias, 2005). Since the member states decide in common the criteria, the indicators and the benchmarks and formulate the evaluative processes, they accept external controls in policy planning. In doing so they incorporate mechanisms of surveillance and conformity in sensitive and critical sectors of social and educational policy (Hostens, 2003; Badham, 2003).

The setting-up of the Lisbon agenda constitutes a critical situation of the EU's symbolic, discursive and political/administrative control in the arena of education and in society. It draws its legitimation from the common interest approach of the member states and is closely connected with the neoliberal technocracy-based

paradigm, which is rapidly transferred from the economy to education and training through benchmarking practices and OMC technologies. Thus the European educational landscape is gradually dominated by ‘regimes of truth’ and ‘systems of knowledge’, which introduce, reproduce and legitimise the technocratic rationale in order to establish a modern European *Panopticon* based on technologies of governmentality, surveillance and control.

EDITORIAL INTRODUCTION: INDUSTRIALISATION, KNOWLEDGE SOCIETIES AND EDUCATION

Robert Cowen

What is the relationship between the world of work and education? An answer from a Dane might be that he had worked hard to merit his place in the shield wall; an answer from a *samurai* that, because of the understandings he had acquired from his new *sensei*, his opponents now came easily onto his sword.

Irritation at such apparently flippant answers to such a sensible question is a mark of how modern our ‘comparative education’ is.

We assume that comparative education must be studying the world of work but our sense of history and of social structures in comparative education is so limited that (apart from noting that agricultural economies still exist) we think of the question – about the relationship of the world of work and education – as meaningful in terms of two systems of, and symbols of, modernity: the educational system and ‘the’ industrial system. By the world of work we do not mean the world of the workers, soldiers and peasants – but just the workers.

Thus our answer to the question, what is the relationship between the world of work and education, rapidly shortens historical time; quickly takes us into mobility studies – as if all societies at all times were ideologically organised around an ethical imperative of upward social mobility; and soon brings us to the question of how ‘relevant’ educational systems are for the world of work.

Thus the major ‘research’ questions and answers rapidly fasten on (i) social stratification and blocked or open social mobilities; and (ii) on the ‘goodness of fit’ of educational systems for the social and epistemic basis of a certain kind of production system. Rapidly the crucial strategic questions – once the assumptions of the starting point are accepted – become

- (a) Can education contribute to the economic development of societies?
- (b) Does the acquisition of certain kinds of educational qualification increase, over a life-span, the earnings of an individual? and
- (c) What kind of educational system does the economic system demand?

The first question has produced a major literature, which ranges over the conventional literature on ‘development’ and the demonstration that investment in education will lead to economic growth. The question becomes interesting comparatively when the

answers address such places as Japan after 1868 or suggest that the reasons China was so slow in 'developing' was because of Confucius.

The second question can only be answered after schooling systems have been in place, as social inventions, for some time, and it has mainly been asked for 'capitalist' societies. Thereafter, it takes quite technical answers, which do not easily lend themselves to a comparative understanding using historical and political and sociological interpretations of a range of societies. Answering the question has been very much the territory of economists. The literature is large but it is not complex as a comparative literature because it does not try particularly hard to understand the ways in which the numbers that answer the question are culturally embedded.

The third question represents an astonishing rearrangement of how the world is seen and what education is for. 'What kind of educational system does the economic system demand?' is not, of course, a universally applicable question – the Taliban were not asking it, Iran for some time has mainly concerned itself with other questions, and the cultural traditions of Norway and Denmark (though they are different) have not normally prioritised this question since recovery from the relative poverty of the late nineteenth century. Some societies – the former USSR and much of the eastern socialist bloc – are recovering from one version of an answer to the question, whilst taking up, rather rapidly, alternative answers to the same question. But certainly professionals in some societies (e.g. England) are living out the question and its local answer (compulsive extreme neo-liberalism) in increasing astonishment and irritation at its effects on the health, social services and educational systems.

There is a variant on this question which is what kind of educational system does the economic system produce? If for the moment we slide by the determinist assumption embedded in the question, then there are four answers.

One answer is, 'nothing very much' – as in Cambodia of the Pol Pot, or Sparta, or Athens, where the concept of 'the educational system' needs a major exegesis and where those forms of education which were offered were based on first-principles other than the economy.

A second answer is a vocationally oriented one in an industrial age – as in those countries which embraced at the policy level, and also implemented, versions of poly-technical education in, for example Albania, Bulgaria, China, Hungary, Poland, the USSR and Vietnam.

A third answer is one which reflects in its relatively simple stratification of educational institutions some of the simplicities of the stratification of economic institutions – such as the schooling systems of Western Europe from, say, 1929 to 1970, or most of Latin America from, say, 1890 to 1990.

The fourth kind of answer is an overdetermined one: a schooling system whose structural opportunities, curriculum contents, pedagogic and evaluative modes, are deduced from one first principle currently called 'the knowledge economy'. This is an economic first-principle, in which the correct – sociologically correct, historically necessary, culturally promising – forms of education are being construed through a deductive rationality (Cowen, 2005). The university and its governance become crucial – and new roles for the State must be defined.

Max Weber (Gerth & Mills, 1967), in a classic interpretative and comparative note on the Chinese *literati*, showed the relationship between 'rationalisation', economic systems, educational patterns and educated identity (especially elite identity) in the

distinctions he drew between the education of the cultivated and the education of 'the expert'. The proposition that comparative education should, following C. Wright Mills, aim at forms of understanding which capture the intersection and interpretation of social structures, historical forces and individual identity is brilliantly met here.

Thus we now have a new challenge: what is the relationship between economic systems, education systems and educated identity? The question is not a relatively complex question about the relationships of some inputs and some outputs from the educational system to and from the economy, but a really complex question which asks about the political economy of identity; the relation of the state and the university and the economy; the forms of governance which relate the three; and the space arenas within which this happens (including notions of the regional state and its governance modes).

The question about the world of work and education includes questions about how the world of work is ideologically presented as a challenge to education – the notion of a knowledge society – and the international discourse which has been generated around it (on transnational, regional and national levels). The complex questions include the relative determinism of deducing the shape of educational systems and their teaching contents and pedagogic modes and evaluation styles from a first principle – the knowledge economy – and asking if these processes can be escaped, or resisted, and thus asking, what are the educational alternatives?

Of course it is possible to say that the prime responsibility of comparative educationists as a special type of policy advisers is to assist in the formation of skill systems by the collection of international evidence about which skill formation system is the best and so on; but this is not a question or a questioning. It is merely a positioning of comparative education as an applied science at the service of funders.

The question remains as it did for Durkheim, Marx and Weber: what are the historical trajectories of the relationships between economic systems and educational processes and identities (including educated identities and selection and socialisation processes) and what are the implications of this for the human imagination, notions of community, authority and legitimation, as well as the sense of the sacred?

The question is sharp at the present moment because we seem to be faced with a very clear deductive rationality (i.e. a totalising principle): that ALL educational systems and most of their details must be deduced from a particular definition of an economic future.

Clearly – like all deductive rationalities – this version of how to define an educational system by 'reading' an economic system is clear, enthusiastically endorsed and unwise. Some of the processes of the ideological construction of notions of the economy and education, the university, regions and their significant relationships, and the emerging consequences are explored in the chapters in this section.

INDUSTRIALIZATION AND PUBLIC EDUCATION: SOCIAL COHESION AND SOCIAL STRATIFICATION

Jim Carl

The expansion of public education and industrialization went hand in hand. After all, had not the pioneering philosopher of free-market capitalism, Adam Smith, foreseen good reasons at the outset of the industrial revolution for nations to educate their populations? “The more they are instructed, the less liable they are to the delusions of enthusiasm and superstition,” he argued. “An instructed and intelligent people, besides, are always more decent and orderly than an ignorant and stupid one” (Kandel, 1933: 51). Before the industrial age, provision of formal schooling virtually everywhere was scarce – dependent on tuition and fees, voluntarist, and usually limited to males. Education belonged to the church in feudal Europe, and with seven out of every ten workers engaged in agriculture, the slender surplus enabled only small percentages of people to earn their bread through the written word (Bloch, 1963; Cipolla, 1993). Although some states, especially in Protestant regions, required villages and towns to keep schools, such edicts were subject to the wants and resources of the localities, and often had little material effect. With the growth of industry, support for public education grew, and the result was a transformation of schooling from limited provision into widespread and hierarchical educational systems (Katz, 1987).

Precise relationships between industrialization and the rise of public education are difficult to pin down, however. If we take as our unit of analysis the long nineteenth century that stretches from the dawn of the industrial revolution to the eve of World War I, then we discern a general correspondence between the spread of industry and the rise of mass schooling. The industrial revolution sparked prolonged, rising rates of productivity, first in the British economy and then in continental Europe, the northern United States, and Upper Canada (Madrick, 2002). As educational access widened, the education of women increased, the study of the classical curriculum declined, and, by the twentieth century, the importance of schooling for both national economic development and individual mobility took on the status of an “education gospel” (Grubb & Lazerson, 2004: 1–2). Gains in income and wealth during the industrial age made possible larger public expenditures for the welfare of the general population, and all governments considered schooling in their expanded social calculus.

But it was a political and cultural question as to what purposes taxes would be applied: Internal improvements? Poor relief? Old-age pensions? Popular education? While the industrial revolution generated the surpluses that contributed to the demand for educational expansion in the trans-Atlantic world, it was other factors – social,

cultural, and political – that dictated the pace (Muller *et al.*, 1987). Adam Smith, for example, did not herald education for its direct economic utility, but, rather for its potential to stabilize society. In the rise of the new educational systems, social cohesion was central to the schooling directed to every child, whereas schooling's selective upper reaches ensured that educational distinctions grew in importance as markers of social stratification.

Thus, when we view the growth of public education with either the nation-state or the region as the unit of analysis, the role of industrialization as a causal factor becomes less apparent. As is well known, there has been a long-standing mismatch in the industrial age between what is learned in school and the skills required on the job (Easton & Klees, 1992). Moreover, in the long nineteenth century rates of industrial and educational growth do not necessarily correspond. Britain was the first society to industrialize, but Parliament did not put England and Wales on a path toward universal primary education until the last third of the nineteenth century. Conversely Prussia, a largely agrarian society, led the world with its extensive system of primary schools for most of the eighteenth and nineteenth centuries, despite its industrial backwardness compared to England (Rury, 2005; Boli *et al.*, 2000). In the United States it was the rural areas of the Northeast and Midwest (but not the South) where schooling reached the highest percentages of children in the first half of the nineteenth century (Reese, 2005). And in many of the oldest secondary schools, colleges, and universities in the Atlantic world, there were reactions in the nineteenth century that strengthened the classical curriculum and rejected science. Philippe Aries (1962) reminds us that a template of schools had already extended their importance with the advent of new constructions of family life in early modern Europe. Industrialization breathed life into patterns of schooling that had already been set in the emerging market societies, and only in limited instances – the founding of engineering schools, say, or the existence of short-lived factory schools – did schooling mirror industrialization exactly.

Due to the chronological mismatch and because of the dearth of industrial educational forms, comparative historical studies of the origins of public education do not posit industrialization as the direct causal factor. National citizenship and social control within a changing economic order – this is the continuum that receives the most emphasis (Nóvoa, 2000). Comparative works in recent years draw from four perspectives to explain public education's rise: state formation, the rise of the western cultural frame, status attainment, and democratization (Carl, 2000). The state formation perspective in education looks to the evolving industrial state in its efforts to forge national identities and legitimize the changing economic order through its leadership in education reform. This perspective is utilized by many writers, among them Martin Carnoy (1992), Bruce Curtis (1992), Ting-Hong Wong (2002), and Andy Green (1990, 1997). Green connects uneven educational development to the efforts of dominant class-fractions to use the state to maintain hegemony and argues that educational development follows “the different modes of state formation in different countries” (Green, 1990: x).

The rise of the western cultural frame perspective emphasizes social, political, and intellectual developments of the Renaissance, the Reformation, and the Enlightenment in the creation of a new form of social organization. This perspective is featured in the

work of John Boli, Francisco Ramirez, and John Meyer (Boli *et al.*, 2000). Two of these authors suggest that public education developed to promote “national unity” and “national success,” through the cultivation of a western cultural frame that emphasized rational individuals, humanized religiosity, egalitarianism, and universal citizenship (Ramirez & Boli, 1987: 3; Boli & Ramirez, 1992). More recently, Stephen Provasnik (2001: 23) also posits schooling as a “constitutive factor in the making of western society.”

If the first two perspectives are indebted to Antonio Gramsci and Emile Durkheim, respectively, explanations that center on status attainment and credentials markets arise from Max Weber. Margaret Archer (1979) suggests that bourgeois groups in Europe competed with religious organizations that sought to protect their role as educators. Sometimes the new “educationally dominant and assertive groups” forced the state to restrict the reach of church schools, sometimes they substituted schools of their own, and sometimes they cooperated with church authorities if the schools were reformed to meet the needs of the assertive groups (Archer, 1979: 143). Randall Collins (2000) argues that credentials markets drive educational expansion and decline: an oversupply of university credentials led to their decline in medieval and renaissance Europe, for example, and competition for scarce credentials has driven secondary and then university expansion over the last two centuries. With a similar focus on secondary and higher education, Fritz Ringer and others bring in Pierre Bourdieu’s theory of social reproduction to emphasize school hierarchies in the reproduction of social distinctions (Muller *et al.*, 1987).

Democratization has been featured recently by economist Peter Lindert (2004) to explain uneven educational development. He considers education as a form of social spending, and his larger project explores the relationship of social spending and economic growth. He argues that the rise of mass schooling corresponds especially to expansions of male suffrage and, in its initial phase of growth, to local control. In the northern United States popular education developed rapidly and early because of well-established voting rights and local flexibility. Lindert applies this perspective to the seemingly undemocratic German states as well, by suggesting that decentralized educational control enabled Germany to behave “like a set of local democracies when it came to primary education” (Lindert, 2004: 122).

This chapter utilizes these comparative histories as well as single-nation studies to examine the influence of industrialization on public education in Europe and North America. This new system of production generated many changes for workers and their families, but for our purposes the most salient one was that it simultaneously created work sites characterized by new routines and forms of control for the many, but also creativity and “highly sophisticated” skills for the few (Berg, 1979: 25). This new industrial order and the social dislocations and political turbulence that it generated gave rise to education systems, ostensibly open to all, that were marked by widening access and increasing standards that gave cohesiveness to national populations, on the one hand, but provided segmented educational experiences that helped to fix young people’s places in an increasingly complex and stratified labor market, on the other. I begin with a discussion of how industrial work processes influenced educational development in England. Roughly following the historic gradient of regional industrial development (Pollard, 1988), I also consider educational transformation in France and then Germany, before proceeding to the United States.

England

The incubator of industrialization was the transition from feudalism to capitalism, the causes of which have long been open to debate, and concern us only to the point that social and organizational changes such as the creation of wage labor and the production of commodities are more important than technological inventions or widespread literacy as prerequisites for industrial development, especially before 1870 (Aston & Philpin, 1990; Madrick, 2002). English textile production in the late eighteenth century was the cradle of the industrial revolution, and here not only were schools besides the point, but industrialization had an initial negative impact on literacy and school attendance (Stephens, 1998). Whether the domestic production of the “putting-out” system or the factory system that arose beside it, owners and parents required the labor of children, and in neither sector was literacy a prerequisite for the work. Indeed, the only education necessary for child workers was brief training on site in the repetitive work processes themselves (Berg, 1986; Wardle, 1976).

Schooling was also largely irrelevant for the skills of the entrepreneurs, capitalists, and managers of the early factories and proto-industrial operations of the late eighteenth and early nineteenth centuries. Skills acquired through apprenticeships and technologies honed through trial and error – together with the social capital necessary to unite capitalist with entrepreneur – were the requirements, not skills and credentials acquired in school. “Even some of the leaders of the Industrial Revolution . . . though skilled craftsmen, were virtually uneducated,” according to W. B. Stephens (1998: 57). For most of the British inventors and innovators, the dissemination of ideas took place in public lectures and via membership in scientific societies rather than in technical schools and universities (Mokyr, 2002). Agitation for the extension of formal schooling was prevalent among many capitalists and workers active in England’s manufacturing region, but the demand for child labor and the fact that the north of England industrialized with a population that was largely unschooled provided powerful counterarguments even in this, the most economically advanced part of the world at the turn of the nineteenth century.

If the technological developments of the first industrial revolution were modest, the social changes wrought by the new system of production were immense, especially for the laboring poor. Here the reliance on wages, the monotony of the work, and explosive urban growth uprooted them from “pre-industrial experience, tradition, wisdom, and morality,” states Eric Hobsbawm (1990: 87). The poverty and disarray faced by the children of this new proletariat was not lost on contemporary observers, many of whom looked to education for solutions (Simon, 1960). Middle-class reformers sought to establish a network of popular education, and in the first years of industrialization some of them went as far as to argue for universal education of the same variety for all classes of people. However, “industrialization led to a deeper and much more explicit class separation . . . than had even been the case in pre-industrial England,” according to Harold Silver. “The conception and provision of education were, like all aspects of society, influenced by the different angles of vision” (Silver 1975: 23). Once the state extended voting rights to men with property in the 1830s, class divisions widened on proposed education reform, with workers arguing most forcefully for primary schools

and adult education that they could control, and the middle-class reformers concentrating their efforts on extending secondary schools and universities for their own children and on advocating elementary schools that they deemed appropriate for the masses. Such reformers often merged their support for popular schooling with their admiration of the factory. In the early nineteenth century, for example, reformers looked to a monitorial system to educate large numbers of poor children cheaply. Proponent Joseph Lancaster and others claimed to have perfected a method by which hundreds of children of all ages and abilities could be taught in a single room via “the division of labor applied to intellectual processes” (Kaestle, 1973: 12).

Yet, the middle-class admiration for the factory and the promise of efficient schools at low cost were not enough to bring primary education to the English masses. Laissez-faire political outlooks remained popular among national elites. Most, but not all, historians agree that voluntarism – religious or otherwise – was not enough to generate mass schooling (Green, 1991; West, 1975). Within the voluntary system that prevailed until 1870, however, the working class strove to educate itself and enrollments increased in a variety of schools across England (Lacqueur, 1976). The state extended its reach only gradually into primary education, initially with the series of Factory Acts in the first half of the nineteenth century to encourage the schooling of children who toiled in the mills, then with the 1870 Education Act that created public school boards and authorized them to establish elementary schools where there were none, and finally with compulsory education in 1880 and the abolition of fees in 1891 (Simon, 1965). These developments roughly paralleled extensions of the franchise for men in the 1860s and 1880s (Lindert, 2004).

In the literature on industrialization and schooling in England, delays in educational development often figure prominently in explanations of England’s relative economic decline *vis-à-vis* the rest of the industrialized world. In fact, several scientists and industrialists of the nineteenth century, some of whom were products of the better-developed Scottish educational system, lamented the dearth of technical education compared to the rest of Europe. England relied for most of the century on an apprenticeship system in manufacturing augmented by part-time technical schools (Green, 1997). As England entered what Fritz Ringer (2000: 47) calls the “high industrial phase of modern European education,” extending from the 1860s to the 1920s, older schools across Europe “found themselves confronted by a group of younger rivals, whose curricular emphases were relatively ‘modern’ or ‘practical.’” In response to the brisk economic growth of Germany especially, the English state abandoned its laissez-faire approach and began to establish technical schools in earnest by century’s end. Along with higher education, the tripartite system of secondary education that included exclusive “public” schools, endowed grammar schools, and expanding higher grade elementary schools began slowly to link students to technical jobs in manufacturing, but it was the commercial, governmental, and professional sectors that welcomed the bulk of the graduates, some of whom were women (Lowe, 1987). Even the aristocratic public schools extended their enrollments to sons of professionals and industrialists, and there is little evidence to suggest that the gentlemanly public school ethos dissuaded students from following their fathers into similar careers (Rubenstein, 1993; Honey, 1987). Working- and middle-class demands for schooling in accord with

an economic system that was rapidly industrializing and bureaucratizing made inroads into secondary and higher education, but within a system in which the public schools, endowed grammar schools, and ancient universities retained their exclusiveness and their classical curriculum (Kazamias, 1966).

France

In France at the end of the old regime, it was not at all evident that England had overtaken it in manufacturing power. To the north and west of Paris, in a region extending into Belgium and Germany, a similar transformation to proto-manufacturing and the factory system in textiles proceeded, augmented by adequate deposits of coal and iron ore (Pollard, 1988). Moreover France's population, while not as literate overall in the eighteenth century as England's, was as interlaced with church schools and educated subjects in its northern region as one could find anywhere in the world. Except for the smallest and most isolated communities of the French interior, villages provided at least a modicum of funding for a teacher, and in the larger towns this was fleshed out by private and charity schools (Maynes, 1985). As to schooling beyond the elementary level, the monarchy had established a series of military, mining, and civil engineering schools that were truly pathbreaking, and the secondary schools and universities, while disrupted by the expulsion of the Jesuits in the 1760s, provided similar provisions to those of other Western European societies for the education of elites (Artz, 1966; Barnard, 1969).

The revolution and resulting warfare to 1815 did much to postpone France's industrial development (Schama, 1989), whereas in education this period was punctuated with false starts in popular education and institution building for the schooling of elites. The educational legacy of this era was the principle of the secular state over the church, which interrupted the extension of schooling for all even as it accelerated the development of technical education and a unified system of secondary and higher schools. Assemblies in Paris generated two well-known plans, attributed to Talleyrand and Condorcet, that called for primary schooling to be made available to everyone, male and female, but deepening crises of authority prevented their enactment (Bailey, 1988). The anticlerical thrust at the end of the eighteenth century disrupted the supply of teachers and curtailed church revenue, thereby reducing the numbers of primary schools, something that Napoleon did little to remedy in spite of the lingering revolutionary spirit of equality and his rapprochement with the church. Technical education, on the other hand, expanded with the founding in 1794 of the *École Polytechnique* and then other schools. Napoleon's imperial state bolstered secondary education with its network of *lycées* in 1802 and its codification of a hierarchical educational system, the *Université*, that placed all schools, secular and religious, under centralized state supervision (Green, 1990).

The French state mandated provisions for mass schooling in the 1830s, 1860s, and again in the 1880s, with the latter decrees by education minister Jules Ferry making primary education compulsory and tuition-free. In this expansion, several trends related to industrial development. In departments with relatively high commercial and industrial activity, state and church provided more schools and enrolled more pupils

than in the departments most isolated from emerging markets. In the industrial districts themselves, however, school attendance was often lower relative to nearby commercial towns and villages due to children working in the mills. Although France's only factory school law, passed in 1841, mandated part-time instruction, it was not widely enforced and owners could limit instruction to one hour daily. The distinction in school provision among departments across France diminished in the second half of the nineteenth century as state requirements penetrated the rural areas (Grew & Harrigan, 1991; Anderson, 1975). Economic development laid the monetary foundation for educational expansion; state mandates came in the middle of periods of educational growth. The highest rate of growth in the establishment of schools occurred during periods of Restoration and July Monarchy early in the century, but the Guizot Law of 1833, which mandated a school in every commune, increased state and local tax support for education still further (Grew & Harrigan, 1991; Lindert, 2004).

Primary schooling by the end of the nineteenth century became the norm, with enrollments and funding approaching the levels of Germany and the northern United States. In rural France increasing percentages of parents recognized the utility of sending their children to school, especially in terms of access to government jobs and independence from intermediaries when making simple transactions and correspondences (Weber, 1976). The purposes of primary school expansion began to shift at mid-century, so that industrial justifications took their places beside the purposes of citizenship, morality, religiosity, and deference. Reformers began to educate the "sons of workers" for the lowest rungs of the technical occupations, as the middle class tended "to abandon industry for the liberal professions" (Anderson, 1975). For boys and increasingly girls not bound for the *lycées* and beyond, the *écoles primaire supérieure*, common in larger towns after 1833, made room for commercial study, and later, the *écoles pratiques de commerce et l'industrie*, also extending from the primary schools, provided vocational training for skilled work and commercial duties (Green, 1997).

Sharp class distinctions between primary and secondary schooling remained for younger pupils, however; nothing like common schools for French children in the early grades appeared until the 1920s. Secondary and higher education for the rest of the century continued on elite paths that emphasized the liberal arts at the base and technical and commercial expertise at the apex. The *lycées* maintained their positions of high status even as the *Université* increased the study of the natural sciences, so that a third of the students prepared in a scientific curriculum by the 1880s. However, French, Latin, mathematics, and philosophy maintained their privileged positions. Distinctive to France, the *grandes écoles* in the nineteenth century expanded over the nearly moribund universities – the *grandes écoles* were highly selective institutions that essentially enrolled sons of professionals, industrialists, and bureaucrats, and they did so with unique mixtures of the liberal and the technical. For admission, academic preparation and entrance examinations relentlessly focused on the liberal arts, but once admitted, most *grandes écoles* stressed engineering, applied science, and business and public administration (Ringer, 1979; Bourdieu, 1996). Although most of the captains of the French economy and polity, by the early twentieth century, received schooling in commercial and technical subjects, selection for such study remained wedded to bourgeois membership and traditional academic disciplines rather than to the practical needs of industry.

Germany

As in England and France, there was turbulence in the late-eighteenth-century German countryside in the shift to a market economy, even though the development of water- and steam-powered factories lagged behind England by a generation or two. A few regions experienced proto-industrialization in textiles, with some schools combining reading and religion for part of the day and wool and flax spinning for the remainder. Meanwhile, estates in the east consolidated to harvest grains more efficiently for export. Significantly, such changes in the division of labor occurred within states, especially in Prussia, where the leadership already encouraged elementary education for peasants and workers. Whereas in England, elite positions that opposed state schooling for the masses had the upper hand throughout the first phase of industrialization (Kaestle, 1976), Prussia and other German states favored compulsory schooling of “the lower orders,” so long as it “inculcate[d] obedience and diligence” rather than a desire to leave the agricultural or proto-industrial workforce (Melton, 1988: 114). Military defeat in the Napoleonic Wars propelled schooling further, with the expansion of the *Volksschule* system and the creation of a Prussian educational bureaucracy that aided nation-building efforts (Green, 1990).

Moreover, the German states advocated elementary schools that inherited a pietist tradition, one that may have differed from the outlooks of the rulers and their high clergies but was in accordance with the bulk of the common people. Schools, and the teachers and students within them, remained organized along confessional lines through World War I (Melton, 2001; Lamberti, 1989; Kennedy, 2005). Combined with a greater degree of local control, relative church-and-state unity may explain why workers and peasants acquiesced to funding and sending their children to state-sponsored elementary schools to a greater extent than their counterparts in England, and why, in the early nineteenth century, the German states had the most extensive system of primary education in the world.

Sharp industrial expansion did not occur until the 1850s to the 1870s, however, when the regions of the Ruhr, Saxony, and Silesia led the way. This roughly coincided with the rise of imperial Germany. It is therefore easy to overestimate the development elementary education prior to mid-century: Frederick II of Prussia may have announced his famous compulsory school edict for rural children back in 1763, but lack of efficient transportation networks and necessary revenues for social spending meant that schooling was not universally available (Melton, 1988). The ability of local authorities to raise taxes through their own school boards rather than depending on the imperial state to do so for them translated into some regions (especially in the urbanizing and industrializing west) with extensive networks of elementary schools, while elementary education in the eastern agricultural regions with large estates generally lagged in funding and enrollments, a reflection of local elite’s reluctance to have schools interrupt labor supplies, in spite of Prussia’s desire to Germanize children in the Polish areas (Lindert, 2004). In the west the state aided school attendance at mid-century by restricting child labor in factories and requiring young workers to attend school part-time (Lamberti, 1989).

German secondary education also benefited from state support that strove to tie the schools more closely to the social structure. Von Humboldt made the nine-year *Gymnasium* a state institution, for example, with an examination that certified students for university study and state bureaucracies. Subsequent curricular reforms made greater room for the study of the natural sciences in these classical institutions than did the English public schools (Green, 1990). The *Gymnasium* mainly enrolled sons of members of the learned professions and highly placed civil servants, but new forms of secondary schooling emerged at mid-century, especially the *Realschule*, which drew a fine line between emulating the high-toned academic culture of the *Gymnasium* and preparing their more commercially and industrially minded clientele with curricula that had a greater scientific focus. For boys who left school early and for those who remained to graduate and even attend university, this emerging system of academic secondary schools had close links to labor markets, not in terms of what was studied, but rather in terms of educational credentials that corresponded to occupational ranks pioneered in the civil service and then extended to commercial and industrial bureaucracies (Muller, 1987).

Other school forms and reforms beyond the elementary level had closer industrial applications, in that what was studied had as much importance to technical, commercial, and managerial work as the educational credentials. In part-time continuation schools for the male graduates of the *Volksschule*, for example, much of the curriculum centered on “vocational training for future workers in agriculture, industry, and commerce” (Albisetti, 1996). Spurred on by the 1897 Handicraft Protection Law, the German state established a system of vocational education and certification centered on both the school and the firm (Hansen, 1997). This well-articulated network of vocational education for blue-collar occupations emerged parallel to the academic secondary schools. At the tertiary level, imperial Germany founded a network of *Technische Hochschulen* (essentially polytechnical universities), and within the older universities, scientific study with industrial applications burgeoned: industrialists underwrote *Göttingen’s* Association for the Advancement of Applied Physics and Mathematics, for example. But the demand for engineering and scientific expertise could not be met by higher education alone; a host of proprietary technical schools and industry-supported business colleges emerged in the 1880s and 1890s to tighten the connections between managerial and technical skills learned in school and the leading-edge chemical and electrical industries (Albisetti, 1996; Mokyr, 2002; Gispén, 1989).

United States

In the United States, where industrial and educational development after the Civil War proceeded at rates that eclipsed European growth, the education system maintained a degree of autonomy from the logic of capitalist development, but to a lesser extent than the educational systems developing on the European continent. United States educational provisions at the primary, secondary, and tertiary levels equaled or surpassed the most educationally advanced countries in Europe, including Germany, which American education reformers sought to emulate beginning in the 1830s, so that

by World War I even secondary education was becoming a rite of passage for a majority of adolescents, male and female (Jeismann, 1995; Reese, 2005; Lindert, 2004).

Leaving aside, for a moment, the large regional variations that such generalizations about the United States mask, what accounted for such sharp educational growth? As is well known, the United States differed from many European nation-states in several respects after the Revolution: no hereditary aristocracy or monarchy, a Protestant identity but no established church, the absence of an insulated and identifiable bureaucratic class, a heavily decentralized governmental system, relatively high levels of male suffrage, a heavy reliance on immigration, and expanding frontiers, all of which checked the opposition to mass schooling (Green, 1990). Moreover, the market revolution permeated the new nation almost from the beginning, and this reinforced an ideology of individual self-improvement that was popular across a wide cross-section of the public. Not only did this generate further demand for schools, it helped to cement a widespread belief that schooling should be closely linked to the world of work (Sellers, 1991; Cohen, 1999; Finkelstein, 1991). These characteristics helped to shape a widely diffused system of popular education that drew, at once, more elite and mass appeal than its English counterpart, and one in which access was determined more by culture than by class. In other words, as a growing nation that encompassed several linguistic, religious, and ethnic groups from Europe, Africa, Asia, and North America, educational reformers sought “civic cohesion” in the midst of “contentious democracy,” even as they shaped systems marked by racial and cultural hierarchies (Tyack, 2003: 3).

Although it is difficult to make an airtight case for correspondence between industrialization and educational development in American primary education, there are nevertheless strong links between the two. In the northern United States before the industrial revolution, where small landholdings of pietistic Protestants of various denominations predominated, rudimentary schooling was already widespread (Axtell, 1974; Cremin, 1970). The three decades before the Civil War witnessed the birth of a factory system in cotton textiles, the concentration and systematizing of the manufacture of other commodities in larger workplaces, the reliance in the growing cities on immigrant labor, and, with the canal and railroad boom, the growing lure of the market for northern farmers. At the same time the district schools, supported locally through a combination of property taxes and tuition, became a target of educational reformers, as did the urban schools, which featured greater class, cultural, and gender distinctions than their rural counterparts. Influential social leaders who sought to standardize and centralize the primary schools during these years, such as Horace Mann of Massachusetts, generally had the support of factory owners and merchants, even though urban school enrollment rates tended to lag behind those of the rural district schools (Bowles & Gintis, 1976; Kaestle & Vinovskis, 1980).

Conversely, in the southern states, the industrial revolution concentrated agriculture onto a single, slave-grown crop for export; southern legislators viewed mass schooling as a northern institution inimical to the social stability of a southern agricultural economy whose most dynamic sector rested on un-free labor. Although the “freed people’s educational movement” of the 1860s put the southern states on the road to mass schooling (Williams, 2005, p. 6), the response of southern elites to demands for education within a diversified commercial system of “wage labor and market production”

resulted in schooling on a racially segregated and highly unequal basis (Leloudis, 1996, p. xii). Although the footprint was smaller in the common schools of the northern states, here too racial segregation accompanied industrialization (Douglas, 2005).

Common school reformers in the Northeast and Midwest succeeded in transforming rural and urban schools into coherent educational systems with a modicum of centralized control. Although this “common school revival” did not bring with it a spike in attendance rates or school construction, state centralization was necessary to push the increases beyond what could have been accomplished through local, voluntary efforts alone. Moreover the common school movement that swept northern states standardized primary schooling through the reformers’ advocacy of graded classrooms, careful record-keeping, and the beginnings of formalized teacher education (Kaestle, 1983; Katz, 1987). For white Protestant children living in the northern United States, common schooling became nearly universal by mid-century. Although the consolidation of this system corresponded temporally to capitalist development, educators packaged their delivery of the rudiments of reading, writing, and arithmetic in a wrapping of discipline, religious piety, and respect for the nation rather than preparation for mill and market.

In the early nineteenth century, secondary and higher education consisted of a smattering of Latin grammar schools, a vibrant network of often-coeducational academies, and a well-diffused collection of men’s colleges organized along denominational lines. Institutionally, the most striking changes of the next hundred years were the rise of the public high school and the birth of the modern research university. Unique among the educational systems discussed, secondary education in the United States evolved upwards from the common schools instead of outwards as responses to schools monopolized by the aristocratic and professional classes (Golden & Katz, 1999). Instruction in Latin had already waned in secondary schools in the decades straddling the Revolution; most families that could forgo their children’s labor sought a curriculum that was both practical and academic, and this meant that English and science took their places beside classical study (Reese, 1995; Nash, 2005). The academies generally drew their students from a cross-section of the middling classes (Beadie & Tolley, 2002), but advocates of the common schools painted them as elitist in their efforts to absorb them and build high schools as “people’s colleges” – the capstones of the public system (Reese, 1995: 57).

Many bourgeois families accommodated the common school reformers’ agenda for secondary education. Partly, this support was attributable to the dearth of academies with large endowments (steady tax support ensured institutional stability for a secondary sector that had been dominated by the more entrepreneurial academies), partly it was attributable to the persuasiveness of the high school boosters’ meritocratic rhetoric (selective admissions based on academic achievement played well in the Jacksonian democracy at the same time it preordained that middle-class sons and daughters would have a leg up on the academic competition), and partly this was due to a limited tradition of church-supported secondary schools at mid-century (Reese, 1995; Terzian & Beadie, 2002). By the time of the second industrial revolution around 1900, the groundwork for the comprehensive high school already had been laid. The decline of paid labor for adolescents contributed to burgeoning high school enrollments in the first two decades of the twentieth century. School leaders responded with

a differentiated curriculum of vocational, domestic, commercial, and college preparatory courses within a single institution, and this along with widespread suffrage and acrimonious relations between management and labor usually blunted efforts to build separate, tax-supported academic and vocational schools for US adolescents.

In the mid-nineteenth century, high schools competed with academies, normal schools, and colleges for students, but colleges and universities began to supplant high schools at the top of the pyramid by century's end. Since economic developments caused many business owners and farmers to view their economic positions as precarious, parents looked to protect their offspring through educational credentials, first at the secondary level as an entree into salaried positions in the growing manufacturing and commercial sectors, and later, in the early twentieth century – when working-class sons and daughters enrolled more frequently in the high schools – at the tertiary level, which gave middling families the added benefit of a secure route to the professions (Labaree, 1997; Brown, 1995). Industrial growth provided the necessary foundation for the colleges to meet the growing demand. The concentration of wealth provided colleges with vast new endowments and the creation of educational foundations expanded curricular offerings and brought order to the new system. The federal government boosted support for applied research in agriculture, engineering, and mining with a series of land grants that began in the Civil War but greatly expanded in the 1890s. The leading colleges themselves brought professional schools within their orbits and, via their interest in admissions from the high schools, became important players in secondary education reform. Offerings in technical education, while not yet at the same level, perhaps, as the leading schools of continental Europe, contributed to the exchange of expertise between the new American universities and the largest corporations (Thelin, 2004).

Conclusion

Industrial growth made the development of mass schooling possible in European and North American states; the economic surplus enabled states to make good on their earlier Enlightenment goal of forging national identities for the populations contained within their borders. The challenge of concentrating on the role of industrialization in the growth of public education, however, is to avoid the pitfalls of economic functionalism. Although schooling expanded its importance for both individual socioeconomic rewards and regional and national industrial development over the course of the nineteenth and early twentieth centuries, there are no ironclad relationships between what is learned in school and economic growth, or between what is learned in school and what workers do on the job (Bills, 2004). Neither growth in the complexity of the division of labor nor increased economic productivity triggers qualitative and quantitative changes to the education system in any immediate way.

There are two buffers between educational and economic systems that make their relationships complex and diffuse. First, school systems are creatures of the state, whether in the ecclesiastical state of medieval and early-modern Europe or the civil state in ascendancy since the eighteenth century. The give-and-take of elite and popular

demands enlarged the scope and reach of the state in the industrial age, endowing its authority and power with the legitimacy of a mediator. Struggles in the relations of production became, increasingly, buffered through the state's bureaucratic mechanisms, including its shaping of knowledge through the institution of the school (Apple, 1996; Carnoy, 1984). Second, educational systems have their own autonomy and logic. Autonomy, in that schools are an ancient institutional form – capitalist development did not bring them into existence. Logic, in that academic tradition inherited from the past serves as a powerful counterweight to the vocational demands of students and the requirements of employers. Even within the technical, professional, and vocational turns that have marked secondary and higher education over the last century, the liberal arts continue to assert themselves in the curriculum (Labaree, 2006).

It is these two buffers – state formation and institutional autonomy – that make it important for comparative educators to pay close attention to history, for it is in the historical-comparative studies of the growth of educational systems in a variety of regions and nation-states that variations and differences can be uncovered. Pursuit of a single causal factor, such as industrialization, can only illuminate general, long-term trends. For a finer-grained analysis, tempering such singleness of purpose with careful historical study of the entire milieu – cultural and political as well as economic – yields richer understandings. For example, the thesis of an emerging western cultural frame as the elemental force of educational expansion since the Renaissance, developed by sociologist John W. Meyer and others at Stanford University, is valuable for understanding global trends in education. However, such an emphasis on schooling as the crest of a new western social organization tends to mask important regional and national variations. Some of the variations are hinted at here, such as Anglo-Germanic distinctions in vocational education or Franco-American differences in the relationships of professional schools to universities. To reiterate, comparative works that address state formation and enduring educational forms inherited prior to the transition from feudalism to capitalism hold the most promise for explaining the similarities and the differences in the comparative history of public education.

Social stratification and social cohesion endured as twin features of the systems of public education that developed in the industrial age. Access to the highest reaches of educational systems, where professional and technical preparation occurred most systematically, filtered through courses of study in elementary and secondary schools that remained relentlessly academic, especially in the knowledge that received the highest status. Yet the leaders of educational systems also sought to socialize every child to the new economic, social, and political patterns that reorganized the nation-states of the Atlantic world. In the long nineteenth century, then, the result was systems of public education that contributed to the cohesiveness of nation-states even as they emerged to determine and legitimate new forms of social stratification in societies undergoing rapid industrial change.

INDUSTRIALISATION, KNOWLEDGE ECONOMIES AND EDUCATIONAL CHANGE: A NOTE ON ARGENTINA AND BRAZIL

Márcia Cristina Passos Ferreira

This chapter will discuss, by describing aspects of Brazil and Argentina in the period 1950–1990, some of the ways in which economic ideas, ideologies and systems are related to educational systems.

The theme of the chapter, at its broadest, is a puzzle about whether the patterns of educational systems in Brazil and Argentina are directly deducible from two discourses – one about the nature of the ‘industrial society’ and the other about the nature of the ‘knowledge economy’. Both these discourses had their roots in international debates, but, it will be suggested, they were both made local, and contextualised, and became different. In other words they were both ‘domesticated’ in different ways in Brazil and Argentina.

Clearly the terms ‘industrial society’ and ‘knowledge economy’ have ordinary – that is, academic – meanings. They are not merely political slogans, or the labels for policies. So there is some point – before moving on – in stabilising the routine academic meaning for both terms. They can be located in mainstream (and well-known) academic literature.

The concept of ‘industrial society’ was well sketched in a classic text of the 1960s:

Modern industrial societies are distinguished in their structure and development from others of comparable complexity, principally by the institutionalization of innovation – that is to say, by the public and private organization, on an increasingly large scale, of scientific research in the service of economic and military growth. (Halsey *et al.*, 1961: 2)

In other words, the academic concept, here as used by sociologists, reflects a shift in an industrial economy from manual to technical and scientific skills, a change which has serious implications for the kind of qualifications required by students entering the job market. Traditional forms of education, in which bodies of skilled craftsmen, aided by labourers or apprentices, work under the supervision of foremen, yield to a more complex structure and are turned to the new objectives of the modern economy.

Thus, from this academic and sociological perspective, educational systems might become similar because of industrialisation. There is an implicit ‘convergence’

and even a determinist ‘convergence’ thesis here which ought – by extension – to apply to Argentina and Brazil. Historically, both have undergone similar processes of economic change from an economy based on agriculture to increasing industrialisation.

And of course within such a theory, ‘education’ is also relocated sociologically in a specific way: education itself is given unprecedented economic importance as a source of technological innovation, and the educational system is increasingly geared to providing a labour force and acting as an apparatus of occupational recruitment and training.

Similarly – about 20 years later – another definition of economies was constructed. It has been argued, academically, that during the 1980s, a new economic world order emerged as a result of globalisation. This new economic world gained a new classificatory term: the knowledge economy.

The ‘Knowledge Economy’

The ‘knowledge economy’ as defined by Giddens is one in which much of the workforce is involved not in the physical production or distribution of material goods, but in their design, development, technology, marketing, sales and servicing. An economy in which ideas, information, knowledge underpin innovation and economic growth (Giddens, 2001: 378).

In analytical terms, the implication of this is that modern economies are powered by the work of ‘symbol analysts’ in areas like designing, marketing or servicing which require intellectual rather than physical skills. Symbol analysis requires knowledge of information technology and computer skills – but more importantly the ability to think abstractly, to analyse and to conceptualise.

Similarly a ‘convergence’ proposition is under construction here: because of the nature of such economies, education is judged to be even more important – and must be of a certain kind. Thus we have two historical moments, in which a definition of an economy is offered (e.g. ‘industrial society’). It is defined academically; and as a discourse it becomes a shaper of educational systems. Did this happen to Brazil and Argentina?

‘Industrial Society’ and Education

Thus the analysis of this chapter tries to indicate how a fairly clear academic idea (industrial society, knowledge economy) becomes an international idea, a discourse which affects countries – and which as it affects countries is absorbed differently in terms of politics and institutionalisation and thus produces ‘different results’.

The chapter, in other words, analyses these processes of ‘domestication’: the absorption and shaping of a common discourse for reform in these two countries – in different ways – at a particular historical period. Following this, the patterns of the educational reforms are defined, including the reforms of vocational-technical education.

The Economy and Industrial Development in Brazil

Industrialisation on a significant scale began in Brazil during the First World War (1914–1918) and its objective was to serve as a ‘substitute for imports’ – there was a

great expansion in heavy industries in this period (Baran, 1957: 8). After the 1950s, the rapid industrial expansion and growth of big multinational corporations disrupted the local socio-economic structures. Economic development, however, depended on foreign investment and large companies were set up in Brazil, which made new demands on public services (Barnett *et al.*, 1975: 35–37).

However, the changes were not merely economic. As Barnett *et al.* (1975: 35) point out, industrialisation led to the emergence of new social alliances, demands on the state and political movements, such as populism. This was one of the effects of the growing power of the urban middle and working classes.

In general terms, the educational policies were designed to restructure the educational systems so that they were suited to the economic and social changes brought about by the ‘industrial society’ (and modernity).

The expected link between education and economic development was implicitly expressed in the resolutions drafted in Regional Conferences of UNESCO’s in the early 1960s. For example, the Santiago Conference on Education and Economic Development, in 1962, recommended adopting the numbers of enrolments in secondary schools as the criterion for measuring social and economic progress in each country in Latin America (Gimeno, 1983). Brazil was in the first and worst group, with an enrolment figure of less than 13% of pupils of attendance age at secondary schools. Argentina was in third group with enrolments higher than 25% (Gimeno, 1983: 31).

The figures in Brazil implied the need to reform education, and the reforms in secondary schools stressed training-for-work as a means of responding to the requirements of economic development in the region (Gimeno, 1983). Ianni (1975) showed how in the 1950s and 1960s Brazil faced a great challenge to create an industrial economy, which led to *desenvolvimentismo*, a political ideal of that time that supported a strong industrial, national economy, until its ‘domestication’ was interrupted by the 1964 military coup.

The Brazilian Political Scene After the Military Coup of 1964: Domestication

After the military coup of 1964, there was a new economic model supported by the industrial elite, military authorities and middle classes backed by international or state-owned companies (Cardoso, 1975). During this period, increasing authoritarianism restricted access to the decision-making process, and only powerful economic interests were able to influence the technocrats when they came to define economic policy. Cardoso (1975: 196) argues that, after 1964, the Brazilian state was reorganised as a hybrid system of oligarchical interests (multinational corporations), powerful state-owned corporations and an authoritarian government.

This alliance shaped educational reform and involved vocational education which was strongly influenced by this model of economic industrialisation. Moreover, social policies and reforms were viewed as a means of compensating the social groups which had not directly benefited from economic development. The purpose of these policies,

in the view of specialists (Cardoso, 1975: 127), was to create stable conditions which would not impede economic efficiency.

The regime set about a full-scale ideological campaign, with efficiency as the main criterion for all its policies (Fiechter, 1975). Through Education Law 5692/71, which introduced vocational education, the authorities sought to demonstrate their concern to address social demands, in a period of political stagnation and repression (Black, 1977), but in the context of an annual increase of GNP of up to 10%. The rapid growth or 'economic miracle' resulted from an expansion of consumerism and exports, as well as the freezing of workers' wages (Saviani, 1987: 23). It was characterised by authoritarianism and a strong belief in economic development with the aid of international capital. The government also sought to create legitimacy through social measures to incorporate the lower strata of society.

It was in this context that the discourse of 'industrialisation' and its relation to vocational education was 'domesticated' in Brazil. In counterpoint, how did the international discourse move into the context of Argentina, and what happened?

The Economy and Industrial Development in Argentina

The Argentinian industrial sectors depended on the interrelationship between the discourse of the 'industrial society', educational growth, the need for industrial skills, and politics. The country had experienced rapid economic decline since the 1920s, accompanied by a high rate of recent immigration, and was in search of a new national identity. The politics of Peronism explains how the discourse of 'industrialisation' was domesticated in Argentina and applied to educational reform. This general motif is repeated later in the nationalistic military dictatorships of the 1960s and 1970s.

During the Peronist period (1945–1955), the purpose of increasing technical and vocational education was to encourage industrial development and make Argentina 'economically independent'.

Rein (1998: 16) describes the Peronist doctrine of *Justicialismo* [social justice], as consisting of a threefold aspiration to social justice, economic independence and political sovereignty. This doctrine aimed to transform Argentina's economic infrastructure by abandoning an exclusive reliance on agricultural exports in favour of industrial development (Di Tella, 1999: 255). In the view of Rein (1998: 17) industrial development combined with continued agricultural exports would ensure economic growth.

There followed the *Plan Quinquenal* [five-year plan] designed to boost local industry and agricultural exports whose market price was high, in the 1940s, and thus finance modern technological imports. Technological advances, an improved energy supply and modern means of transport would lead to greater industrial growth. The plan also included protectionist policies to favour the growth of local industry (Romero, 1994: 143). Di Tella (1999: 268) shows how, as a result, local industry grew and the volume of industrial production rose in the 1940s from 61% in 1939 to 76% in 1945 and 100% in 1948. However, industrial growth in the Peronist period followed the pattern of the early 1940s, caused by the country's isolation during the Second World War (Di Tella, 1999: 264). The value of exports from USA had fallen from 109 million dollars in 1941 to 31 million dollars in 1943 (Rosa, 1992: 307).

This historical context shaped the development of Argentine industry, and as Romero (1994: 143) points out, most industries were improvised workshops. Despite the inefficiency caused by the lack of raw materials and technical equipment (Rosa, 1992: 307), industry expanded rapidly, partly assisted by protectionist policies which hindered foreign competition.

However, the relative growth of the industrial sector was largely due to the expansion of small businesses, such as the textile sector (200 small businesses with 62,000 workers). The textile industry, which remained the leading industrial sector, employed 50% more workers in 1946 than in the late 1930s – mostly unskilled females and young men (Rosa, 1992: 167). However, industrial growth was uneven since some sectors (like steel and paper) did not just rely on unskilled labour and there was a failure to improve the country's power supply and transport system (Luna, 1984: 78–80).

Thus industrial growth in the period relied mainly on labour rather than on technology. According to Rein (1998: 20), the economy had deteriorated by the end of the 1940s and it was realised that the industrialisation and modernisation programmes had never really materialised; the country's foreign-currency reserves were depleted and inflation was rising.

Perhaps surprisingly, the agricultural sector did not benefit much from reform either. By 1946 the effects of Castillo's 1942 measure to freeze rural rents (Luna, 1984: 175) meant that many small farms needed government support or credit to expand (Lumerman, 1994: 188).

Lack of investment and modern technology resulted in a gradual decline in agricultural productivity. There was no increase to meet the significant post-war demand for agricultural products. As a result, by the end of the 1940s, Argentina found it hard to meet home demand and increase exports at the same time, let alone finance industrial modernisation.

Argentine industrial growth did not experience technological advances in the Peronist period either. As Luna (1993: 56) shows, this period witnessed an increasing demand for labour and a 30% increase in wages leading to an expansion of light, labour-intensive industry (Romero, 1994: 147). The sluggish industrial growth meant that there was no significant demand for educated labour (Donghi, 1994: 123).

However, limited demand for skilled labour does not account for the intense educational progress that occurred in this period. The aims of the educational reforms were political and reflected one of the aspirations of *Justicialismo* which was the integration of the poorer sectors of society. Rein (1998: 16–20) states that the First Five-Year Plan, echoing Perón's desire for a 'socially just nation', attempted to implement a 'new social policy which would make men more equal and would offer them equal opportunities'.

The *Derechos del Trabajador* [workers' rights] (1949) sanctioned the reforms the state introduced in 1947 to protect workers' rights. The social project included wage increases, improved working conditions and food subsidies (Rein, 1998: 24). Thus, through *Justicialismo*, Perón attempted to win the support of the working class and also to make schools accessible to all Argentinians regardless of their economic status.

Overall, then, during the 1950s and early 1960s in Brazil, and 1945–1955 in Argentina, there was a debate about creating an 'industrial society' and hence becoming

modern. The logic of accepting this vision, and the discourse, led to a desire to change the educational systems and to adapt them to the needs of economic development. This was accompanied by foreign financial assistance for educational reform in both countries, following the rationale that education would help industrial expansion.

However, the notion of the discourse of the 'industrial society', which is contextualised in this section, has shown that the crisis in education mirrored the crisis of the whole social system and educational reform was a means of overcoming this crisis.

Finally, after adopting these policies and under increasing pressure for reform, by 1970, Brazil and Argentina were beginning to face the world of the 'knowledge economy'. What happened?

The 'Knowledge Economy' and Education

In very broad terms, the processes were similar: the 'new idea' began to affect the way education was regarded, and – when framed as a discourse – the range of 'educational reforms' possible. In principle, the new discourse should have led to the same pattern of educational reforms, in both countries including vocational-technical education. How and why it did not is the concern of the next part of this chapter, together with the economic systems of both countries in the late 1980s and early 1990s.

De Moura Castro (1998: 9–10) argues that Brazil and Argentina found themselves in a new 'world situation' in which knowledge had become the main factor of production and the principal means that nations could obtain a competitive advantage over their rivals. Filmus (1994) attributes this change to the high speed of scientific-technological progress, the internationalisation of the economy, and the emergence of a new ideology about production and labour organisation.

This, it was argued, had implications for education, since a lack of qualifications among the people would exacerbate existing inequalities. In Brazil, Pastore (1995: 31–38) predicted that there would be a growth in demand for personnel with a post-secondary education, and a decline for those with less formal education. Research into the modernisation of technology in five Latin American countries revealed that the gap between the newly qualified and 'unqualified' was growing significantly wider (Ascelrad, 1995: 50–62).

The globalisation of the world economy and the new international division of labour seriously harmed the economy of certain regions and productive sectors in Brazil (Rattner, 1995: 19–22), while others were introducing technological and organisational innovations (Gallart, 1997: 15). This, it was argued, would result in greater social polarisation, where a minority would earn a high income and have an affluent lifestyle, while the majority would not be able to satisfy their basic needs (Rattner, 1995: 25–28). A reason for this was that the 'big companies' were producing high-tech goods or offering sophisticated services that required very skilled labour.

In rational terms 'knowledge' can be seen as the main factor of production and education as of fundamental importance for economic competitiveness and employability. For example, the problem of unemployment is regarded as being a problem of lack of qualifications. Hopkins (1987: 15) raises the prospect of an 'uncertain future' in which

in the view of Delors (1998: 48) the only thing that could be predicted was a ‘rapidly changing world’. As a result of this discourse, lifelong learning and education for work are advocated as remedies that do not involve ‘practical’ education but rather a general education based on the transmission of ‘competencies’.

In this discourse, the need for change in education is largely expressed in economic terms and particularly with regard to the preparation of a workforce and competition with other countries as shown in the following extract from an OECD text:

Only a well-trained and highly adaptable labour force can provide the capacity to adjust to structural change and seize new employment opportunities created by technological progress. Achieving this will in many cases entail a re-examination, perhaps radical, of the economic treatment of human resources and education. (OECD, 1993: 9)

This discourse about the ‘knowledge economy’ regards schools as a part of the national economy rather than simply belonging to the ‘welfare society’, with the role of creating ‘human capital’ that can be invested in production and turned into profit. In the case of Brazil and Argentina, this discourse has prescribed a set of parameters for educational thought and action to limit ideas and practices; moreover they have been domesticated and became part of social struggles and political strategies.

The Domestic and the International

This domestic debate was apprehensive about the future and strongly influenced by the international ‘debate’. The World Bank was very clear about what a ‘knowledge economy’ is:

A knowledge-based economy relies primarily on the use of ideas rather than physical abilities and on the application of technology rather than the transformation of raw materials or the exploitation of cheap labour. It is an economy in which knowledge is created, acquired, transmitted, and used more effectively by individuals, enterprises, organizations, and communities to promote economic and social development. (World Bank, 1998d: 1)

The OECD was also aware of what was happening (and by extension, what should be happening):

The knowledge economy is transforming the demands of the labour market in economies throughout the world. In industrial countries, where knowledge-based industries are expanding rapidly, labour market demands are changing accordingly. Where new technologies have been introduced, demand for high-skilled workers, particularly high-skilled information and communication technology (ICT) workers, has increased. At the same time, demand for lower-skilled workers has declined. (OECD, 2001: 1)

This sent clear messages for economic competition and, hence, for the reform of education. Moreover, to compete effectively in this constantly changing environment, workers must be able to upgrade their skills on a continuous basis.

In contrast, in Brazil and Argentina, the domestic debate emphasised social problems and intellectual resistance. In Brazil, during the 1990s, the new methods of production were regarded as the cause of unemployment. Yet, although the problem was largely seen as a lack of qualifications in the workforce, some like Ascelrad, thought that the discourse of competitiveness in Brazil was used to justify 'a productive rationalisation based on the intensification of work' (Ascelrad, 1995: 61). 'Labour' was portrayed as an obstacle to efficiency, and concern about the social progress of workers was seen as obstructing competitiveness. The failure to train workers was used to justify the massive redundancies in companies and workers could be blamed for firms losing their competitive advantage (Ascelrad, 1995: 50–53).

In Argentina, for example, Gore (1996: 108–110) argues that during the 1990s, there were very many 'badly trained' people whilst there was a need for qualified workers. Thus, there was a huge number of unemployed on the streets, while companies were unable to fill their vacant posts because they could not find the 'kind of people they needed' (Gore, 1996: 108). In fact, as Gallart (1997: 3) and Filmus (1994: 9) noted, only a few people were involved in the new technological processes. As a result, a high proportion of the public was destined either to become destitute or to be forced to work in the 'black' economy (Gallart, 1997: 4).

Yet the job losses in Argentina, particularly where low qualifications were required, set in motion processes that could create other jobs (Filmus, 1994: 9–10). Thus there was a need for higher educational standards and better qualifications.

Etcheverry (2001: 36) stressed the importance of the time spent in formal education, and a person's income. A study by the Inter-American Development Bank in Buenos Aires and its suburbs showed that in the 1990s, the incomes of those who had completed six years of education were 35% higher than those with no formal education. Moreover, someone who had completed 12 years of studies earned 80% more than someone without formal education. Finally those with 17 years of education (including university) earn 160% more than someone without any formal education (Etcheverry, 2001: 35–37).

In Brazil the link between less education and lower incomes was 'widespread' (Birdsall *et al.*, 1996: 11). Barros and Ramos (1996: 193) stated that education could explain up to 50% of the inequalities of earnings in the country. Birdsall *et al.* (1996: 35) noted that the unequal distribution of income was perpetuated by the 'quality gap' between the education provided to poor and wealthy children. As a result, it was believed that a high standard of basic education could result in a more productive labour force, faster economic growth and less inequality (Birdsall *et al.*, 1996: 35).

The issue of educational reform can only be understood in the light of the socio-economic and educational inequalities of the two societies.

The Implications of the 'Knowledge Economy' for Education

There was some doubt about the capacity of society to generate employment in the industrial sector both in Argentina and Brazil during the 1990s. Despite the increase of

productivity in manufacturing industries, there was a decline in the number of people employed in this sector (Gallart, 1997:3). Since industries that require intensive, low-cost labour were not deemed to be viable, low-cost labour was ceasing to provide a competitive advantage for a nation (De Moura Castro, 1998: 10).

Thus, by the late 1990s, the literature in Brazil and Argentina advocated a model of development based on knowledge, scientific-technological advances and a new system of education. In other words, a new discourse began to emerge. Filmus (1994: 5) stressed the overriding importance of skills in providing a competitive advantage. Thrurow and Reich cited by Filmus (1994: 5) argued that the crucial productive resources of the twenty-first century – capital and new technology – would spread rapidly around the globe. Of course, people would relocate themselves, but at a slower rate than other ‘factors of production’. The location of the essential industries of the new century (microelectronics, biotechnology, telecommunications and informatics) would depend on existing human resources (Filmus, 1994: 5).

The enhancement of ‘human resources’ was seen as essential for Brazil and Argentina to participate competitively in the increasingly knowledge-based global economy. Failure to improve people’s skills could result in these countries being separated from the networks of the international economy. Filmus (1994: 11–12) noted that, in Argentina, knowledge had become the main requirement for sustained development. He suggested that ‘being at the margin of this knowledge means that one is excluded from all possibilities of participating actively of this growth’ (Filmus, 1994: 15). In Brazil, De Moura Castro (1998: 13) cited President Cardoso as saying that educational systems in Latin America must either ‘invest heavily in R&D and endure the “information economy” metamorphosis, or they become unimportant and unexplainable’.

It was not only that people needed more education, but also a different kind of education. For example, it was said that the concept of literacy had changed in the new discourse. During the period of the ‘industrial society’, someone who could read and write basic texts was considered to be literate. On the other hand, in the new ‘knowledge economy’, people can only be regarded as literate if they are capable of interpreting a manual (Pastore, 1995: 38).

It was in this context that the literature in Brazil and Argentina witnessed a major shift in the definition of ‘education’, especially the notion of competencies. These were defined as being halfway between knowledge and action and a set of constantly changing properties that were tested when concrete problems arose in work situations involving uncertainty and technical complexity (Gallart, 1997: 10). These competencies were not easily transmissible because they were a synthesis of theoretical knowledge and concrete experience of the real world. Hence, the definition and transmission of these competencies requires the collaboration of both education and sections of the labour force (Gallart, 1997: 10).

From the perspective of the new discourse, the new labour force required a solid general training, a capacity for abstract thinking and a global understanding of the production process. In addition, workers had to be multifunctional, flexible and adaptable so that they could adjust to different working situations and to companies that were becoming increasingly more flexible (Filmus, 1994: 13–14). It was also noted that there was a tendency towards decentralisation in decision-making, which meant

that workers had to be autonomous so that they could think strategically and respond creatively to shifting demands. At the same time, they should have the capacity to make decisions when faced with unexpected situations and put ideas into practice. In terms of attitudes, what was needed was to be self-disciplined and capable of working in teams. Finally, since students would have to face considerable technological innovations throughout their working lives, they had to have a positive attitude towards continuous learning (Filmus, 1994: 15).

Filmus (1994: 15) recommended that, in Argentina, the whole population should have access to high-quality education. Although more sophisticated employment could not be guaranteed to everybody, it was necessary for everyone to be 'employable' (Filmus, 1994: 14). Gallart (1997: 10) refers to the importance of reducing the disparities between the competencies that are acquired in elite education and those acquired in the public sectors. Llach *et al.* (2000: 188) outlined a plan to construct a society that was more adapted to the challenges of the knowledge society, but over all, a 'more equitable nation'. The literature revealed a consensus in Argentine society about the need for the competencies described above to be taught in the educational system.

In Brazil, transmitting the 'necessary' competencies to everybody was regarded as both a question of equity and an issue of national interest: for the economic benefits of the country, educated workers needed other educated workers with whom they could interact (Llach *et al.*, 2000: 189). Thus it was not beneficial to have a small number of highly educated workers and a low average level of education. It would be more productive to have 'a large pool of moderately educated workers that could communicate effectively with one another' (Llach *et al.*, 2000: 372).

Thus, in Brazil, changes in the production processes and the labour force were seen as liberating workers from hierarchical relations and automated work. In addition, the problem of unemployment was described as being rooted in the 'under-qualification' of workers.

It was assumed that the problem could be addressed by 'adapting' the educational system, so that it transmitted the competencies that were required for work in the 'knowledge economy'. Amongst these competencies, autonomy, problem-solving, flexibility and adaptability were identified as the most important since it was believed a number of technological revolutions could be 'predicted' in the near future. These included an increase in the international competitiveness of Argentina and Brazil and an alleviation of the problem of unemployment and inequality.

The Reforms of Education: Domestication and Social Struggle

However, the idea that one particular reform proposal could cater for the interests of all social groups was perhaps simplistic and based on the assumption that all 'social needs' can be identified. In addition, the similarity in the proposals contained within Argentine and Brazilian academic discourses suggested that social changes brought about by the 'knowledge economy' imply similar 'social needs' in both countries. Embedded in this discourse was the assumption that just as the 'needs' of 'industrial

society' could be defined, the 'knowledge needs' could be identified too and these were applicable, with some adaptations, to every society.

Judged from the perspective of the 'knowledge economy', Argentina and Brazil were in a state of social, economic and educational crisis – and a great deal was expected from education. Thus, introducing 'the right changes' into Argentine and Brazilian education to 'adapt' the workforce to the 'knowledge economy' was of crucial importance, since spreading 'quality' education was essential to make these nations internationally competitive, as well as for training responsible citizens, and the employability of the individual.

Hence, the principles within the discourse of the 'knowledge economy' have been treated by the Brazilian and Argentine literature as natural, self-evident facts. Elements of the discourse of the 'knowledge economy' were being used as social strategies – they had been turned into legitimising principles operating within the educational field – and in both countries the curriculum pedagogy and the organisation of the educational system were changed.

The 'Educational Domestication' of the 'Knowledge Economy' Debate

The literature in Brazil and Argentina made a number of criticisms and recommendations aimed at adapting education to the 'knowledge economy' discourse. These ideas were centred in two main themes. The first largely concerned the curriculum and pedagogy, and the second the organisation of the educational system and the institutions themselves.

In Argentina, the first proposal made in terms of the curriculum and pedagogy (especially for secondary education) addressed the dichotomy between general and professional education. Braslavsky (1995: 4) suggested abandoning the traditional view of secondary education, which believed the purpose of education was to give students access to a lot of information, a verbal command of the contents of books and training in the exercise of memory. She thought that 'vocational' tendencies should be rejected too. The discourse required changing occupational profiles so that they encouraged a capacity for abstraction rather than practical skills (Braslavsky, 1995: 4–5).

Braslavsky (1995: 6) believes professional education should be separate from secondary education, in Argentina. The lower secondary school ought to concentrate on transmitting basic competencies that ensure autonomous and effective processes of learning, and the chance to understand and establish abstract models. At the same time, professional education should be less bureaucratic and more flexible, adopt a modular structure and employ competent workers to teach specific practical abilities (Braslavsky, 1995: 7).

Similarly, in Brazil, secondary education was criticised for lacking identity and being detached from the requirements of the modern world. The encyclopaedic curriculum of secondary schools and its pedagogy were censured for only preparing students for entrance to university (Bastos, 1998: 305). Teaching students to learn, and preparing them to acquire new technologies to produce goods, services and knowledge were mentioned amongst other new roles that secondary education should undertake.

In Brazil, there was also a sense that educational improvement was always lagging behind changes in the labour market and that the acquisition of higher educational standards had not resulted in more labour opportunities for the young. This situation (which can be seen in the whole of Latin America) can be attributed to the expansion of education in ways unrelated to changes in the labour market (Jacinto & Suarez, 1995: 152).

Within the Brazilian academic discourse, there was a definition of an ideal kind of person or 'economic man' designed to address the ideological implications of the 'knowledge economy'. This definition required a curriculum that embraced certain basic competencies and skills that schools should encourage, including critical thinking and creativity amongst its students (Viciani Gonçalves, 1995: 134). Rather than simply transmitting knowledge that was then applied in the workplace, the school should be an innovative environment, a laboratory that constructs new knowledge through the relationship between student and teacher and a place where theory can be combined with practice (Bastos, 1998: 305). It was even recommended that vocational education should apply pedagogical methods based on the creative use of practice to teach the fundamental theoretical paradigms required for the 'knowledge economy'.

Within the Brazilian academic discourse, knowledge was given greatest priority. Thus, great importance was attached to 'learning to learn' and lifelong learning. The stress on content should be reduced by giving more space to a kind of pedagogy that laid emphasis on the learning process and encouraged the student to learn more (Pieroni & Achcar, 1995: 120–130). This was explained on the grounds that there was a need to prepare professionals to be able to handle technological changes in their everyday practice and throughout their careers (which implied having the ability to absorb new information and be trained to keep abreast with changing trends in education) (Rachid & Githay, 1995: 64–70). As a result, people's timetables would be divided into working time, leisure time and learning time. Thus, it was considered essential that students should 'learn how to learn in school' (Pastore, 1995: 37).

In the literature, it was believed that Brazil could only adapt to the 'knowledge economy' if this education encouraged flexibility, adaptability and autonomy. According to Bastos (1998: 306–310), schools should realise that they did not have a monopoly of knowledge and must form a relationship of mutual learning with the productive sector. He agreed with Ferretti in suggesting that the radical changes and greater flexibility in the productive sector should be reflected in the educational system at all levels (Bastos, 1998: 311–320). Rachid and Githay (1995: 70–84) noted that entry into an unpredictable world required people to have a global understanding of the process so that they could apply their knowledge in future situations. At the same time, Jacinto and Suarez (1995: 153–155) recommended that students should acquire greater autonomy, as well as being capable of being organised and working in teams.

In Argentina, both Braslavsky and Gallart agreed with Tedesco (2001: 2) on the need for secondary education – and the whole educational system – to abandon its endogamy, put an end to the institutional isolation of the school and strengthen its links with social communities and the world of production and work (Gallart, 1997: 12–17). However, Etcheverry warned against an 'utilitarian' idea of knowledge, since 'contemporary pragmatism' left us trapped in the dichotomy between 'useful' and 'useless'

knowledge. Everything that was deemed as not useful for making money was discredited by parents and children (Etcheverry, 2001: 88). The school became an institution that prioritises the acquisition of 'tools'. However, the author suggested that the apparently practical advantage of aligning public education with the labour market is an illusion. By concentrating on technology – on computers for example – one would simply produce obsolete graduates (Etcheverry, 2001: 89).

In Argentina, there was an educational dilemma between 'theoretical' and 'practical' knowledge which, in the opinion of Gallart, derived from a false conception of knowledge. If knowledge were understood as something directly related to action, where 'to know' meant to be able to handle the necessary languages so as to be able to act competently in determined domains, the distinction between intellectual and manual capacities would be blurred (Gallart, 1997: 9–10).

In this context, Gallart outlined the following requirements for secondary schools in Argentina: a capacity to understand the relationship between the abstract and the concrete, an intellectual ability to handle abstraction and symbolic operations, a capacity to make quick decisions, an ability to organise other people and the use of materials, machinery and financial resources (Gallart, 1997: 8).

However, both Gallart (1997: 9) and Etcheverry (2001: 49) noted that the abilities that the school needed to foster, such as problem-solving and learning to learn, could not be acquired in a vacuum of 'content' (Etcheverry, 2001: 50). There had to be a balance between factual knowledge and the capacity to make 'socio-historical interpretations' (Gallart, 1997: 8). Reverting to the example of computers, Etcheverry (2001: 50) observes that any literate person with a reasonable capacity of abstraction and logical thinking could learn how to operate a computer program at any age.

Yet, Gallart (1994: 17) warned against compiling a 'curriculum by aggregation' in Argentina, since incorporating new subjects, like technology or ecology, could easily lead to a strengthening of 'encyclopaedism'. She suggested that new content should be included in the curriculum in a creative and imaginative way, across the basic competencies. Gallart (1994: 18) also observes that the basic cognitive competencies that were required for the future had not changed substantially since the curricular reforms of the 1970s. Like Etcheverry (2001: 49), she argued that reading, writing, mathematics and basic general knowledge were amongst the weakest areas of secondary education in Argentina.

Thus, in both Argentina and Brazil, it was considered essential for education to relate to its context, and the world of labour and production and the traditional 'encyclopaedic' curriculum was condemned. There was evidently a need for a curriculum more closely linked to the question of students' employability. However, this did not imply having a practical curriculum, but rather one based on competencies like learning how to learn, and including values such as creativity, flexibility, autonomy and a capacity to work in teams.

Another aspect of the 'knowledge economy' is the advocacy of a new style of management and organisation within the educational system and its institutions. Decentralisation and school autonomy were seen as the guiding principles of this new approach.

Tedesco (2001: 2) stresses the radical nature of the expected educational changes in Argentina. Instead of reforming pedagogical methods and revising the content, it

was necessary to work out the right pedagogical and institutional formulae to improve content, methods and institutional design. Furthermore, he questioned the value of dividing the educational system into primary, secondary and tertiary levels. The needs of society and the requirements of scientific and technological progress established a need for lifelong learning, and this refuted the idea that knowledge could be acquired progressively through a lineal sequence.

In this context, it was suggested that the system should be decentralised, with enhanced central agencies and a significant growth in the autonomy of the schools (Ministério da Educação Brasil, 1999: 18). The strengthening of the institutional autonomy of schools was justified on two grounds. First autonomous schools could make better use of ‘increasingly scarce resources’ (Gallart, 1994: 16–17). By this was meant that schools should have more freedom to draw up their institutional projects and decide how to devote their time, as well as how to employ teachers and organise their work (Gallart, 1994: 16–17). A further point was that institutional autonomy would make it easier for communities to be involved in school decisions (Braslavsky, 1995: 4).

Preti (1999: 21) pointed out that a ‘neoliberal educational policy’ has been implemented. In a society which values knowledge as a form of merchandise and which also attaches great importance to social and labour relations, the ‘neoliberal project’ has persuaded society that education was the only means of tackling the economic crisis (Preti, 1999: 22). Preti said that, from the perspective of the neo-liberal logic, schools were ineffective in a society where those with the ‘greatest knowledge’ were the winners, as a result of a management crisis. Thus schools had to carry out administrative reforms to become competitive, and enter the job market.

In the case of Argentina, a wide range of problems have arisen from the decentralised organisation of the educational system, with a number of different strategies being suggested to overcome them. These notions of decentralisation were not only perceived and recognised as legitimate, but were also internalised as natural phenomena and thus used as a social strategy.

Preti (1999: 21) argues that the ‘neoliberal discourse’ imposed a hegemonic ideology and questions if education has had much influence on employability and economic competitiveness and decentralisation policies. He also referred to the indispensable need for continuous ‘retraining’, as well as the new qualifications required for work, like learning to learn and a good general training (Preti, 1999: 21). Thus, although Preti struggled to escape from the ‘knowledge economy’ discourse, his work finally came to terms with it.

Although some authors made different recommendations, each author incorporated the debate about – and even the discourse of – the ‘knowledge economy’ into his or her work. As a result of the varied but intense interest in the ‘knowledge economy’, it became an ideal the Argentinian and Brazilian academic world absorbed, and indeed helped domestically to construct.

Conclusion

This chapter has traced an idea in motion, mainly by sketching four themes: identifying the idea of both ‘industrial society’ and the ‘knowledge economy’ as academic concepts, noting how they became a ‘discourse’ at international level, and indicating how

these two discourses were domesticated in two places, Argentina and Brazil, in particular time periods.

As the discourse was domesticated and absorbed by local politics, it changed and it certainly led to different educational policies, including vocational technical education policies in the two places. In other words, important academic concepts changed into powerful political discourses at international level, and in both countries, but their domestication – their political acceptance and reformulation – led to new and different patterns in the two educational systems.

During the 1960s, Latin American countries sought to meet the requirements of an ‘industrial society’ by setting out (especially Brazil and Argentina) their ‘modern’ and ‘progressive’ economic goals. The result of this restructuring was that their educational policies were adjusted to cater for the needs of national development and the discourse of the ‘industrial society’.

Brazil

In Brazil, it was easy for the post-1964 military authorities to introduce their policies because there was no significant opposition from bodies such as democratic trade unions or student movements – this represented a very particular political form of ‘domestication’. During the 1960s, in Latin American countries, there was a new impetus to meet the requirements of economic development and enter the international market. Brazil, in particular, strengthened its economic policies and undertook a process of financial and administrative restructuring, the purpose of which was to link education policies to the interdepartmental goals of the national development plans. As a result, vocational education programmes were introduced to prepare workers through non-academic courses. Stress was laid on preparing the pupils for the labour market, on the assumption that there was an increasing need for qualified personnel. However, the educational planners had failed to anticipate that there would be a resulting mismatch between the economic model and the training programmes for jobs.

One aspect of ‘domestication’ is clear: by means of vocational education, the government of Brazil assumed it would be possible to expand secondary education, as well as tackle social problems such as unemployment. The introduction of vocational education policies occurred when Brazil was undergoing a phase of industrial expansion. However, the ‘economy’ was not able to cope with the uncontrolled expansion of school enrolments. Vocational education which had formerly been seen as a remedy, took on a more sophisticated form: in fact, there were several reforms to give all secondary schools a vocational character with a view to preparing young people for work.

The other aspect of ‘domestication’ was that the vocational education programmes and the school system were based on foreign models, and introduced by policymakers as a means to fulfil economic and social needs. These needs arose from the nature of the new companies being set up, industry was dependent on investment from overseas (e.g. the World Bank), and the ideological assumptions of the ‘industrial society’. The policymakers played a key role in the process of introducing vocational education and borrowing a model of educational innovation from the United States. The reforms of the educational systems were part of a package of loans and assistance programmes for economic development.

Perhaps there are two international discourses here – one about ‘industrial society’ and another about vocational-technical education. The obvious research question is whether the two discourses gradually took on an ideological status – served as an ideological tool – in so far as they helped governments to disguise increasing socio-economic inequalities.

Argentina

In Argentina, too, the idea of an ‘industrial society’ was ‘domesticated’, but in startlingly different ways from Brazil. In contrast to Brazil, the rapid expansion of education experienced in the Peronist period (1945–1955) was not closely tied to demands for skilled labour to meet the demands for industrial growth. In fact, neither the large educational expansion nor the development of technical education was clearly linked to the requirements for skilled labour – despite the fact that Perón’s project for national economic growth aimed at fostering industrial development. As Rein (1998: 16) states, ‘[T]he Peronist doctrine consisted in a threefold aspiration to social justice, economic independence and political sovereignty.’ Perón’s plans gave priority to encouraging local industry and included the following: the financing of modern technology through agricultural exports, an improved power supply and modern means of transport, protectionist policies, preferential credit and state subsidies. However – although industry did grow rapidly and intensively – industrial development did not take place quite as Perón had planned.

By the end of the 1940s, the Argentine economy started to decline and the programmes for industrialisation and economic modernisation never materialised. Thus, the modest growth in the industrial sectors and their reduced technological progress meant there was a decline in demand for skilled labour. What is even more striking is the way in which the industrialisation and economic modernisation discourse found political expression: the development of education was geared to serve the political interests of the Peronist state, contribute to social order and foster political stability.

Perón domesticated the industrialisation discourse in a very specific way – claiming to be transforming Argentina into a ‘socially just nation’ and making the state responsible for protecting the weak sectors of society. In other words, the Peronist movement sought to create ‘new Argentinians’ for the ‘new socially just Argentina’ and the education system was an important tool for achieving this objective.

Of course, education also indirectly contributed to economic growth by providing basic skills for life in urban and rural areas. The expansion of vocational and technical education did meet some of the needs of labour while providing completely new career opportunities for the urban middle class. Both *escuelas industriales* [the industrial colleges] and *Universidad Obrera* [the Workers’ University] with their emphasis on applied sciences provided more practical education for those who could not attend *colegios nacionales* [national colleges]. However, although the reforms originally aimed to foster industrial development, this never occurred. The Peronist educational reforms were tied to the social policies of the State.

Thus in the discourse of the ‘industrial society’, the objectives of vocational education, in both countries, were a crucial form of investment but also acted as a political

and social strategy, although in different ways. Clearly, however, the exact patterns of educational reforms were not directly attributable to the discourse about industrialisation. The social and political framing of education altered the emphasis.

In Brazil, the reforms and the role of the state after 1964, during the military period, included both authoritarianism and a strong belief in economic development financed by international capital. In contrast, in Argentina, Perón took political measures that consisted of a threefold aspiration to social justice, economic independence and political sovereignty by employing protectionist policies which hindered foreign competition. Moreover, this domestic and social struggle gave rise to a good deal of inner conflict.

Both Brazil and Argentina found they were under increasing pressure to introduce reforms. However, by 1970 they were beginning to be faced with a new phenomenon – this was the arrival of the ‘knowledge economy’ and its accompanying discourse which required both countries to make a suitable adjustment.

There was considerable evidence that several academics have been debating the ‘knowledge economy’ in terms of the assumptions and expectations of the international discourse. The discourse on ‘industrial societies’ overlaps with the discourse on progress and modernisation and the even less clear concept of ‘globalisation’. However, the educational implications are clear. Notions such as curriculum-based competencies, lifelong learning, decentralisation and school autonomy are recognised by the literature as being legitimate in this new social context.

When analysing educational policies in these countries, the influence of the ‘knowledge economy’ discourse on world outlooks was apparent and it can be regarded as having become an ideology. Moreover, this ideology has acted as the guiding principles for educational reform in Brazil and Argentina since the 1990s and has had a profound effect in shaping educational systems and changing the status of vocational-technical education. Under the ‘knowledge economy’ discourse or ideology, this has gradually given way to a situation where much of education has become training in competencies.

Perhaps, now, we are witnessing convergence?

EDUCATION, JOBS, AND VOCATIONAL TRAINING

Leslie Bash

Introduction

In the last quarter of the twentieth century a state-generated agenda, with a focus on issues of employment and employability, assumed an increasing position of prominence in the comparative education literature. One of the more prominent examples, the 1995 *World Yearbook of Education* (Bash & Green, 1995), offered a range of perspectives, drawn from commentaries on a diversity of contexts, on the relationship between education and work in addition to some of the more salient issues concerning the integration of young people into society. These included:

- The ramifications of global economic and political change
- The impact of industrial restructuring
- Changing labour markets, lifelong learning, and systems of vocational education and training
- Diversity and equality in the transition from education to work

The above use of *vocational education and training* necessitates a working definition based on the conventional view that it comprises: ‘all more or less organised or structured activities that aim to provide people with the knowledge, skills and competences necessary to perform a job or a set of jobs, whether or not they lead to a formal qualification’ (Tessarini & Wannan, 2004: 13).

In signalling the developing impact of globalisation the *World Yearbook* exemplified an expanding narrative which was to reflect, both literally and metaphorically, a growing sense of *fin de siècle*. There appeared to be little anticipation of the kinds of dramatic political events to come (such as 9/11 and the Iraq War) and the ensuing anxieties concerning the apparent alienation of specific constituencies of the young and perceived threats to national and global security. However, it did make an additional contribution to an approach to comparative education that was to focus increasingly upon the unifying consequences of international economic integration.

To place these issues into perspective it may be helpful to open with some comments which would appear fairly evident to those with only a casual acquaintance with a comparative and historical knowledge of education. First of all, questions concerning its connection with the world of work began only to possess meaning once education ceased to be a minority, elite pursuit. Indeed, the classic elitist approach placed a premium on education precisely because it was judged to be irrelevant to the masses.

Thus, the requirement that those in leadership positions receive an education was itself dependent upon an acceptance that the mass of workers did not – and vice versa. Plato's view that a liberal education – intellectual, aesthetic, and physical – would provide the necessary foundation for the guardianship of society has persisted over space and time (Plato, 1955, Book 7).

Secondly, however, there has also been a long-standing view that if the masses were not to be educated they at least might be *trained* in order that they perform their essentially manual labours in an efficient and effective manner. The nature of such training was to be highly prescribed, frequently little more than a process of modelling the tasks to be learned against existing practice: the traditional institution of apprenticeship enshrined in the master–pupil relationship. This institution was to be found in diverse forms but was generally based upon the common notion of mastery, insofar as apprentices were successfully inducted into a 'guild' of practitioners. Essentially, there was the expectation that the pupil would defer to the master as the 'gatekeeper' to the world of recognised craftsmen. Note also that apprenticeship, as with elite education, was gender-specific, being mainly the preserve of the male sector of the population – and many respects this would appear to remain the case. While, in the UK, the recent renaissance of the system (the Modern Apprenticeship) is apparently open to all, neither occupational stereotypes nor the process of gendered occupational segregation have disappeared (Fuller *et al.*, 2005).

Thirdly, subtle changes begin to occur in the narrative. Thus, the term *vocational* was progressively incorporated into the vocabulary of those with a remit for policy and practice in respect of the preparation of individuals for specific occupations. While *vocation* had been previously associated with the notion of a *profession* which evoked the idea of a *calling*, its adjectival counterpart came to have a rather more prosaic meaning: that which pertains to skilled jobs, often with a manual aspect, but ranking below those for which a university education was a prerequisite. Thus, the plumber and the electrician might have been in receipt of vocational *training* while the doctor and lawyer would be expected to have received a university *education*. In this regard, Wolf (2002: chapter 3) notes that policymakers in the developed world have promoted vocational education and training as a necessarily good thing for national economies while at the same perceived as 'a great idea for other people's children'.

The Vocationalisation of the Academy

The apparent rupturing of the boundaries that have conventionally separated vocational training from liberal education signalled widespread changes in the structure and content of work. In addition, it also suggested a more general shift in social relations. In the context of higher education Kazamias and Starida (1992) have identified a process of *vocationalisation* as opposed to that of professionalisation where the emphasis is on preparation for employment. Here, the focus is the market and thus the necessity for a relatively rapid response to its dynamic. Bearing in mind the competitive nature of the global employment market governments which, in the spirit of free enterprise, had previously taken a somewhat *laissez-faire* approach have in recent years sought to

develop regulatory processes. Consequently, diverse occupations, such as teaching, law, and medicine, previously characterised by relative institutionalised autonomy have come under an increasing degree of state control. Garoupa suggests this has occurred, particularly in the latter half of the twentieth century, as clients began to demand more information about the services provided by professionals and where the market is perceived to have failed 'to produce the socially optimal quantity and quality of the professional service. . . . [Thus] some protection for the consumer of professional services is necessary to guarantee quality and mitigate inefficiencies. Protection of consumers frequently takes the form of regulation of the profession and its markets' (Garoupa, 2004: 4).

Other jobs traditionally needing at most a course of work-based vocational training are now the province of higher education. Thus, a specialised undergraduate degree is increasingly a global requisite for occupational areas such as nursing, childcare, catering, and retail management. While one possible implication has been that universities have undergone significant changes to enable assessment according to a skills-based, rather than a knowledge-based, agenda it has also raised the issue of an 'over-educated' population. Chevalier (2000) argues this position as a consequence of having taken a considered empirical approach to the issue of 'over-education', specifically in the context of the match between education, qualifications, and the degree of satisfaction with work. Yet it remains undoubtedly a contested concept, especially in an era where a dominant theme in the political narrative suggests that education is the solution to a good many defined social ills. Yet, it could be argued that the likelihood is that even if there is an apparent mismatch between credentials and the requirements of the job in the short run the nature of work itself will change as a consequence of the increased value derived from a more qualified labour force.

From a comparative perspective, the last 30 years or so have provided a tableau upon which has been written the story of an increasingly global quest to establish and maintain international economic competitiveness. One consequence of this has been an ideological move away from one perception of individuals, whose possession of skills and knowledge contributed to personal and social identity formation, to another perception which marked them out essentially as embodiments of human capital (Wilson & Woock, 1995: 8–9). Just as with any other item of capital, educationists and education policymakers began to speak heavily of such items as investment, evaluation, outputs, and profit.

An increasingly globalised move during the last quarter of the twentieth century towards the marketisation of education and training reflected both the accelerating transnational shifts in production and advances in new technologies. The suppliers of education and training recognised the need for a rapid response to a much more flexible global economy where manufacturing jobs declined in the West as they shifted to the less-industrialised regions or were replaced by advanced technologies. At the same time most Western countries at the centre of global economic activity acknowledged these changes in the formation and implementation of policies even if that acknowledgment was often masked by a view of individuals which marked them out as lacking relevant skills rather than as recipients of a market failure to supply jobs.

It should be further noted that until the demise of the state socialist regimes, Eastern Europe continued to operate, unsurprisingly, in a conventional centralised manner,

regulating both the supply of, and the demand for, labour. Schools, vocational training institutions, and universities tended to be little more than conduits for the deployment of human capital within an economic structure characterised by significant state intervention. Arguably, this resulted in a skewed employment structure and contributed to an economy unable to deliver on either the domestic or international fronts. Of course, the state socialist systems of Eastern Europe were not alone in this *sponsorship* process even though a *contest* process may have preceded it (cf. Turner, 1960). In France, a place at a *grande école* would provide a guaranteed future in the elite sectors of employment, while the Ivy League and Oxford and Cambridge universities continued to perform similarly for the US and the UK respectively. By and large, however, by the end of the twentieth century, the majority of industrialised societies in being committed to marketisation rejected the centralised role of the state, except insofar it was needed to deal with perceived threats to the national social and political order or of threats to the national position in the global economic order.

It was not altogether surprising therefore that as youth unemployment began to accelerate in the 1970s the impetus for the establishment of ‘training’ policies in the West became that much greater. What became known in much of the literature on education and work as the ‘new vocationalism’ was exemplified by the Youth Training Scheme (YTS) in the UK. The ‘new vocationalism’ departed from the conventional notion of vocational training in that its primary aim was not to equip young people with sets of specific skills acquired through an often lengthy period of apprenticeship, which would mark them out as qualified technicians and craftsmen. Rather, the focus was on the development of young people to a state of readiness for employment, as Dale states:

The aims . . . include the need to adjust to a new status, somewhere between work and non-work. The objectives of the new vocationalism are as much occupational versatility and personal adjustment as anything that would formerly have been recognized as skill training. (Dale, 1985: 7)

Thus the YTS and its immediate predecessors appeared to assume that the cause of youth unemployment was lack of relevant skills among the young. Significantly, such schemes did not suggest that youth unemployment might be connected with the overall lack of work opportunities. The ‘new vocationalism’ was based upon the notion of generic or transferable skills (such as those relevant to success in job interviews) and, in due course, was to have an impact upon higher education as universities began to be transformed into managerialist degree-delivery systems.

It was clear, however, that the ‘new vocationalism’ was not simply a political response to an apparent acute phenomenon of youth unemployment. It possibly also reflected a realisation that the economy was increasingly global in character, that comparative advantage was becoming much more fluid, and that ‘jobs for life’ was an anachronistic concept. In the UK context the disappearance of manufacturing which had traditionally accommodated significant numbers of young people lacking formal academic and vocational qualifications constituted a clear change in the socio-economic structure. In their quest for lower costs large multinational corporations began to transfer

manufacturing capacity to regions where wages were significantly lower than Europe and North America. At the same time, new technologies (robotics, computer-aided design and manufacture) additionally contributed to the lower demand for unskilled and semi-skilled labour while also increasing productivity.

This was all far removed from the pioneering approaches to the education–work relationship, as characterised by Dewey in the US and the polytechnicism of the early post-revolutionary period of the Soviet Union. Here, in principle, the world of work was to be perceived as little different from any other area of human activity and, therefore, could be treated as an authentic aspect of the school curriculum. Work experience was not to be equated with vocational training but as a means of enhancement of the totality of learning. Of course, in the case of the Soviet Union, there was an undoubted ideological agenda to polytechnicism (Bash, 1991) while Dewey’s approach blended with the *Gemeinschaft* of the American local community. Also, while the focus remained upon the internal socio-economic structures of both countries, experimentation in education or work was permissible. Once, however, the political-economic elites in the US and the USSR began to see the future in terms of international economic, political, and military competition there was little room for idealism. ‘Calvinistic’ Stalinism – the Stakhanovite exhortation to all workers to increase their productivity – together with the cold war actions of both the US and the USSR combined to provide a backcloth to the competitive race for global dominance in the 1950s and the 1960s. Centralised direction shaped the vocational narrative in the Soviet Union, with a heavy emphasis on science and technology, while, as in other areas, the fear that the Americans could be upstaged in respect of their supremacy in science resulted in unprecedented Federal intervention in education policy in the shape of the National Defense Education Act of 1958.

In the less-industrialised countries the narrative has tended to be of quite a different order. Basic education is often perceived in terms of the development of human capital, both as a vital contribution to GDP and as a contribution to personal income, with the argument reported by Wilson and Woock (1995: 9) that:

[T]he education and skills level of a nation was crucial for its economic development. . . . This simple formula of expenditure on education in developing countries equalling growth still underlies many of the programmes of education and training fostered by international agencies working in developing nations.

Status issues emerged in the early postcolonial context where many parents, as with their counterparts in the industrialised West, had elite aspirations for their children (the law, civil service, and similar occupations). On the other hand, the demand for a skilled labour force, able to maximise manufacturing and agricultural capacity, needed to be recognised by the newly formed nation states, especially in Africa. However, there was an underlying assumption, challenged strongly by, among others, Philip Foster (1965a, b), that the education system was actually in a position to deliver such skills to emergent economies, that it could remedy deficits in the areas of practical engineering and modern farming. Despite the alleged ‘fallacy’ of vocational schooling, it appeared to be particularly attractive to Nyerere’s Tanzania, with its focus on primary education

as the generator of basic human capital, a theme enshrined in 'Education for Self-Reliance' (Nyerere, 1968) which eschewed the need for widespread secondary or higher education. No doubt, given the global perspectives of the twenty-first century, many would now consider these positions somewhat short-sighted, with the unintended consequence of consigning less-industrialised countries to the periphery of the international economy. Indeed, Foster's thesis was quite clear in demonstrating that aspiring school students and their parents understood that some kind of 'elite' education was in their interests. No doubt a macroeconomic approach to the market economy would suggest that such an increase in aggregate educational demand would constitute a positive contribution to national income and GDP with the consequent additional human capital and overall economic demand. The obverse of this is that vocational schooling, while seen as a universal panacea, would simply reinforce a situation characterised by low-level technology, limited productive capacity, and low wages.

However, the exposure of the 'vocational schooling fallacy' in the context of the less-industrialised countries did not prevent its later reinterpretation in the West. That there should be a close fit between education and work is apparently reflected in the *vocationalist* narratives of the last 30 years. It stands in contrast to the traditional view that the manifest content of education merely signalled to employers the potential status of future employees. Thus, the classical curriculum, the conventional preserve of the European middle and upper classes, was a marker for the professions. It mattered little that it was of a 'non-vocational' character; indeed it was precisely because it was directly removed from the world of work that the classical curriculum, paradoxically, was regarded as having particular relevance. The significance of the classical curriculum according to Stray (1996) was to be found in its symbolisation of academic rigour, social aspiration, and self-discipline. The narrative of the early twenty-first century, however, is founded on the assumed *correspondence* between education and work: measured vocational competencies as assessed in programmes of study, from second-level schooling through to doctoral dissertations.

Davies anticipates this when he notes:

that the tendency to 'vocationalise' the curriculum and favour traditional subject specialisms in schools and colleges has led to a narrowing of the academic curriculum and a stress on vocational training. This is an education and training emphasising standards, discipline, attitudes and dispositions compatible with employers' views of the proper characteristics workers and employees should possess. This vocationalisation of learning opportunity has become part of new divisions of certification and at the higher levels of attainment has undermined the liberal approach to higher education which favoured general and humanistic approaches. (Davies, 1997: 8)

Thus, the attempted democratisation of education at all levels and of the process of transition from formal education to employment has inevitably resulted in the proliferation of accountability mechanisms. Accountability manifests itself not least in the assumed process of dispassionate, objective, neutral assessment with patronage and nepotism, while not entirely disappeared from the world of work, nonetheless having

less legitimacy in the early twenty-first century. The process of entry into employment is increasingly formalised, subject to the possession of publicly recognised skills-based credentials, and frequently shaped by the outcomes of varieties of psychometric and other tests.

In the midst of this quest for correspondence between education and work it is clear that a status hierarchy will remain. While the UK government is pledged to introduce a new-style Diploma (Department for Children, Schools and Families, 2007), initially specialised but followed by a more general version, in 2008 to run alongside the existing school-leaving combination of GCSE and GCE Advance Level qualifications, even the Education Secretary (in 2007) warned of its possible rejection as second-best by parents. Echoing Foster's previously mentioned observations of Ghana, the fear appeared to be that the Diploma, while possibly providing some kind of improved preparation for work, would be likely to be associated with the relatively low-status vocational areas. As such, it would track young people into a segregated stream – the 'secondary modern' qualification as opposed to the 'gold standard' provided by GCE A levels. At the same time, a proposed GCSE in construction and building (2007) signalled a number of anxieties and tensions among which are the remedying of skill shortages and the motivation of 'non-academic' students.

In sum, this section has attempted to demonstrate that a profound change has taken place in the relationship between education and work in the late twentieth and early twenty-first centuries. This change is characterised by a shifting context from the national to the global. In particular, the vocationalisation process in the West has proceeded from a focus on 'training' in generic and transferable skills for working-class young people having few or no formal qualifications to one that is now much broader in scope. In brief, economic and employment considerations have now come to dominate the entire educational agenda. Accordingly, attention is now turned to the relevance of globalisation to the changing relationship between education and work.

The Globalisation Problematic

In the context under discussion, globalisation, as partially reflected in the Bologna process (European Ministers of Education, 1999) – the creation of a European Higher Education Area – signals the possibility of the convergence of education systems as attempts are made to implement diverse aspects of harmonisation. As a consequence, schools, colleges, and universities may be perceived as little other than adjuncts of the international economic order. Doubtless, some national superstructural features will remain, reflecting closely guarded cultural legacies. Thus, whichever political direction France will have taken as a result of the 2007 presidential election, it is probable that it will continue to display a certain national distinctiveness despite the pressures of the supposed efficiencies of global economic management and the accompanying American-style work ethic. At the same time, leaving aside assertions regarding corruption in the less-industrialised regions of the world, it might be judged that familial and non-democratic influences will continue to be a significant factor in the school-work transition in various parts of the globe.

Significantly, it is difficult to see how even those countries which are relatively peripheral to the global economy and the transnational networks by which the global economy is constituted can escape the pressures to vocationalise the entire educational system. The overwhelming power of the discourse of globalisation is manifested in continually re-created narratives that signal the urgency with which education should engage with the economic infrastructure. This is despite the wealth of data collected by comparative educationists over the past 50 years suggesting that there is little evidence to indicate a causal connection between increased participation in education and national economic development. Or, as Wolf (2002: 53) notes: '[T]here is no clear indication at all that the UK, or any other developed country, is spending below some critical level, or that pumping more money into education will guarantee even half a per cent a year's extra growth.'

However, this does not appear to have prevented governments from continuing to pursue what Wolf (2004: 330) has considered as simplistic policies rooted in target-oriented and over-centralised control ideologies rather than more sophisticated policies connected with the understandings of students and their parents.

Two key difficulties facing the governments of those nation states concerned with their position in the global economy are signalled here. The first concerns the means by which the education system can deliver the skilled and knowledgeable labour perceived to be required at all levels. The second concerns the means by which all sectors of the population will eventually have access to livelihoods which will meet individually, socially, and culturally defined material and non-material needs. The role of schools, colleges, and universities in each country will differ in detail and will be subject to prevailing educational, economic, and political agendas. In this respect, China, for example, continues to perform an interesting balancing act. On the one hand, it seems to be prepared to foster higher educational development to the extent that it temporarily exports students to the West in pursuit of a significant place in the global market. On the other hand, as evidenced by the 17th National Congress of the Communist Party of China (2007), there appears to be a continued maintenance of close, centralised micromanagement of the internal social and political order. Thus, it seems likely that societal tensions in China will increase as the relationship between education and work is progressively globalised while social, cultural, and political life remains relatively constrained.

In the final analysis, at the level of popular discourse, a global view of the education–work relationship might suggest a continuing belief that a 'good' education enhances employment prospects and, therefore, economic development. At the macro level, governments and other agencies persist in actions which appear reminiscent of Foster's 'vocational school fallacy' as policies are devised and implemented to ensure a better 'fit' between the products of the education system and the demands of the economy. In an era of rapid globalisation, futurology is invoked in attempts to forecast employment needs for the next 10, 20, or 30 years as structures are put into place to ensure the production of the specific stratified labour force required for the middle of the twenty-first century. At the micro level, individuals tend towards action which if not always entirely rational nonetheless reflects a perception of self-interest rather than of the collective. Schooling, even if not consistently instrumental in the achievement

of personal, social, and economic advancement is, at the very least, seen as a means of ensuring employment that will meet the socially and culturally defined basic needs of most individuals. It is here that both parents and children place an emphasis upon what may be viewed as the ‘facilitation of positional advantage’, i.e. ‘the labour market advantage conferred by the *exchange value* of education’ (Williams, 2004). Wolf (2002: 54) puts this more concretely in noting that: ‘[S]chooling and qualifications do signal certain substantive skills – and people’s earnings are related not just to their paper qualifications but also to their relative academic ability.’

Conclusion

Comparative studies of the relationship between education and work no doubt illuminate differences in practice, policy, and ideology. However, as this chapter has attempted to demonstrate, such differences are not necessarily explained through conventional modes of analysis, utilising dichotomies such as ‘centralised/decentralised’, ‘capitalist/socialist’, ‘centre/periphery’. These polar concepts have either ceased to have substantial meaning in the wake of the historical events of the final decades of the twentieth century or else globalisation has resulted in an economic geography that reflects a continuing and increasingly fluid dynamic. The economic convergence resulting from increased global commercial integration has implications for a greater convergence of education policies across national systems. As industries become evermore reliant upon advanced scientific, technological and managerial skills, and knowledge, this is likely to be reflected in the agendas of policymakers. At the same time, public concerns increase with the accelerating pace of change in technologies with the fear that innovative, ‘relevant’ education and training policies are outmoded even before they come on stream. As might be predicted, those countries which are judged to be in urgent need of a close, effective relationship between education and employment and, thus, in need of serious capital and recurrent funding, may be the least likely to receive it. Low GDP and national income combined with a failure to capture a sufficient volume of international inward investment contribute obstacles to educational expansion, as exemplified by the case of Bangladesh (Rabobank, 2005: 2): ‘The country is classified as a low-income country by the World Bank. Although 53% of GDP is generated by the services sector, nearly two-thirds of the population are employed in the agricultural sector (20% of GDP).’

The likelihood is that the wealthier countries will continue to be characterised by education systems which both reflect – and contribute to – relatively higher income levels. This is the case whether second-level schooling is comprehensive or selective, whether the work dimension is a central element in general education or confined to the vocational streams. The relegation, or indeed the elimination, of ideological conflict in this area has heralded a much more fluid situation.

On the other hand, it also seems clear that socio-economic divisions will continue to be manifested in the internal dynamics of educational institutions across national systems and, importantly, in educational and employment outcomes. This might be seen in the adoption of policies to promote *lifelong learning*, a watchword that has

now entered the discourse with the connotation of the provision of a panacea for continuing skills deficits in a context of a rapidly changing globalised economy. While its focus is the post-compulsory sector, lifelong learning impacts upon the twenty-first century educational narrative as a whole. The changed narrative appears to continue to emphasise the education–work relationship through a process of marketisation that places the responsibility for vocational success on individuals as consumers and their take-up of *learning packages* rather than on the quality of employer provision (Ryan, 2003). In the context of the European Union its focus is a set of ‘key’ competences defined as: ‘those which all individuals need for personal fulfilment and development, active citizenship, social inclusion and employment’ (Official Journal of the European Union 30.12.2006: 13).

When unpacked, these are distilled into eight headings:

1. Communication in the mother tongue
2. Communication in foreign languages
3. Mathematical competence and basic competences in science and technology
4. Digital competence
5. Learning to learn
6. Social and civic competences
7. Sense of initiative and entrepreneurship and
8. Cultural awareness and expression

(Official Journal of the European Union 30.12.2006: p13)

It might be observed that the term competence as used here is somewhat broader in meaning than that signalled by conventional usage in that it references mental states rather than just being confined to behaviours. Nonetheless there is the inference that all such competences are capable of being tested and measured, thus reinforcing a progressive shift towards vocationalisation. At the same time, it is also a further shift in the direction of marketisation as learners are transformed into traded ‘commodities’. With the acquisition of ‘value-added’ social and cultural capital, learners enter an increasingly globalised employment arena of bidders and sellers – and one that is constantly shifting. Here, conventional notions of supply and demand together with that of monopolistic competition offer some insights into the relative positions of those with diverse general educational and vocational qualifications at specific moments in space and time. Accordingly, those with internationally recognised advanced skills and qualifications enter with a greater capacity to determine the course of the market in their favour than others whose employment destinies would seem to be almost entirely determined by the market, whose forces are beyond their control.

Thus, the connections between education and work appear to be increasingly reinforced by global patterns. By the middle of the twenty-first century comparative educationists may be examining the prospect of a progressively globalised structure of educational processes geared towards engagement with an increasingly integrated world economic order, while, less convincingly, into an international civic order. Or, more pointedly, it may be necessary for comparative educationists in their quest to

make sense of global patterns of education to heed the observations of Stiglitz (2007) who has noted the uneven consequences of globalisation where economic integration is accompanied by international social segregation and marginalisation.

THE EVALUATIVE STATE AS POLICY IN TRANSITION: A HISTORICAL AND ANATOMICAL STUDY

Guy Neave

‘All animals are equal but some are more equal than others’

Animal Farm

Introduction

Over the past two decades in Western Europe, the Evaluative State has grown, is growing though whether, like the power of one of Britain’s more unfortunate monarchs, George III, ‘it ought to be diminished’ is a question as delicate as it is misplaced. In this chapter, I will explore the historic forces behind this particular phenomenon with a view to getting some purchase over where it is likely to lead us. And this in turn engages one of the most fundamental developments that higher education in Europe has to grapple with today – namely, the rise of what at different times and across different disciplinary perspectives has been variously described as ‘the European dimension’ (Huisman *et al.*, 2000) as the intergovernmental layer (Maassen & Neave, 2007: 135 ff) or even amongst the more metaphysically inclined within the scholarly community, as the ‘supra governmental’ dimension in the affairs of higher education (Maassen & Olsen, 2007: 3–24).

By and large, the Evaluative State on the one hand and the so-called Bologna Process on the other have been treated as separate and watertight issues – and, to some extent, indeed they are. The former quite obviously took shape and matured within in that classical setting of higher education policy, namely within the Nation State. The latter, however, represents a new and very certainly a permanent additional dimension or level of decision-making that both ties in with, whilst at the same time forming, a species of ‘supra ordinate’ layer beyond what for the past two centuries served as the highest level of aggregation in the evolution of the universities in Europe.

... a Double Transition and a Historical Watershed

Once we shift our sights from the Evaluative State as it evolved within the Nation State to its broader setting as a central dimension within the emerging European Higher Education Area, clearly we find ourselves involved in a species of ‘double transition’.

The first involves changes the Evaluative State brought about on the home front. The second focuses on those further adjustments subsequently made to take account of the Bologna Process and the emergence of a European Higher Education Area. There is, however, one final justification for bringing together the Evaluative State and Bologna and it is no minor one. The rise of the Evaluative State, viewed within the evolving Bologna Process is perhaps the last example of policymaking in higher education conceived uniquely as a national venture (Neave, 2006c: 27–46). And though it is difficult to anticipate with any degree of precision where individual national administrations will draw the line between spheres wholly domestic, and those requiring at very least a modicum of benevolent neutrality from other Member States whether individual or collective, the very imprecision serves merely to emphasize this historic watershed.

The Dynamic and the Origins of the Evaluative State

The Evaluative State has as its essential purpose to ensure the continual mobilization of the higher education system by the regular evaluation of its productivity, performance and its usage of public resources. In short, it is a highly dynamic construct. Hence we need to attend closely to its dynamic aspect, if we are to grasp the full import in the shifts it has brought about. As with most things in higher education policy, the Evaluative State unlike Athena, did not spring fully armed from the thigh of Zeus, of the Prince or whatever allegoric figure one cares to associate with the activities of a Nation's administration. The Evaluative State emerged from a number of measures, few of which could, at the time they were taken, be seen as unambiguous pointers to what was to emerge later. In tracing the historical roots of the Western European version of the Evaluative State, one has to admit that the selfsame measures, which later matured into this construct, had greater kinship with the routine husbandry that systems of higher education demand to keep them running than with a self-conscious and deliberate move to place the relationship between higher education, government and society upon a radically different series of principles and operational procedures. Nor were the motives that underlay the drive towards the Evaluative State necessarily as homogeneous as they now appear. Suggesting this begs a few questions. What is the Evaluative State? What were the driving forces that brought it about? How has it changed the relationship between higher education and society?

To answer these central questions I shall concentrate on Western Europe for the plain and simple reason that this is where the Evaluative State assumed its modern and, in all probability, its most sophisticated form. I shall not, however confine my attention there. There are equally good reasons to justify a wider excursion, not least to avoid the charge of parochialism – *l'esprit de clocher* – which is ever present even in studies that claim to be comparative.

Roots

The roots of the Evaluative State are to be found in three closely interrelated crises that in Western Europe reached a head in the mid-1980s. These were first of all the resurgence of social demand for higher education and on a scale far beyond all precedent.

In short, national administrations faced a situation for which they had neither planned nor foreseen whilst their colleagues in finance faced coffers distressingly empty.

If the first wave of the 1960s drove higher education beyond its historic mission of socializing the future political elites and on to the more complex task of mass higher education, the second wave was no less radical in redefining the purpose of higher education in terms of providing access at a level which for certain countries – France being one – by the last half of the 1990s reached universal status. For others, rates of participation at a similar level became the official target of higher education policy. This was the ambition of Britain (White Paper, 2003) and the Netherlands (Kwikkers *et al.*, 2005) – to have more than 50 percent of the relevant age group in what is now fashionable to call ‘Tertiary Education’ by the year 2010. ‘The ‘universal’ stage is commonly held to be attained when participation in higher education reaches 40 percent of the appropriate age group (Trow, 1974).

The second crisis was how to fund so massive a demand – an issue all the more urgent for the fact the main weight of demand did not fall on the private sector – which was relatively marginal in terms of student enrolments in Western Europe – but rather on universities which were state funded and controlled to upwards of 95 percent of their annual income.

The third element underpinning the drive towards the Evaluative State was the question of operational efficiency. Whilst the first two elements – social demand and funding – even with the wisdom that hindsight brings with it, may be seen as largely routine aspects in running a national system of higher education, the notion of operational efficiency was, in the medium term, to provide a powerful lever in moving routine administrative adjustment and accommodation towards what is often fashionably alluded to in the inimitable jargon of technocracy as ‘system re-engineering’. For this notion, see Mungaray-Lagarda (2002).

Operational Efficiency: A Central Concept

Operational efficiency is key to the rapid emergence of the Evaluative State in Western Europe. To put no finer point on it, the emergence of the Evaluative State itself reflects a species of definitional dynamic – or if one cares to view the phenomenon in terms of philosophy or linguistics – as a species of ‘epistemic drift’. What was understood as ‘operational efficiency’ itself underwent rapid transformation both in respect of those dimensions subject to, and brought under, administrative and public scrutiny. For this same reason, extending the dimensions of oversight also entailed extending the range of procedures, measures of verification and assessment that could be brought to bear. If we look closely at the condition of higher education in those countries where the rise of the Evaluative State emerged earliest in Western Europe – Britain, France, the Netherlands – it is clear that the main challenge posed during the mid-1980s was the distribution and usage of resources. From this it followed that the main goal of policy turned around their further optimization – first by cost reduction, and second by measures in rationalizing the national coverage in disciplines.¹ Operational efficiency remained fully in accordance with the usual range of administrative

action – cost cuttings, a halt on the recruitment of permanent staff or their substitution by part-timers (de Weert & Enders, 2004) and closer scrutiny over student input. There were, however, clear signs which entailed accelerating one particular process, which was already operant in certain systems of higher education in Western Europe before the onset of crisis – namely, the gradual detachment of funding higher education on the basis of student numbers and the gradual abandonment of historic incrementalism – that is, the use of an annual adjustment to take account of inflation, cost of living, etc. (Glenny, 1979).

None of these measures, widely applied though they were across systems as varied as the British, the Belgian, the Dutch and the German, can be interpreted as reform of a radical sort, though that is not to deny their often painful effects.² On the contrary, the development of indicators of institutional performance can, in its early stages, be seen not as an alternative to the long-established procedures of system coordination by law, decree, close financial oversight and accounting – systems which some commentators then interpreted as State control (van Vught, 1989). Rather, in its early stages, the ‘new instrumentality’ was conceived more as a supplement, a more sensitive series of pointers that served first of all the internal needs of ‘system steering’. This it would do in principle by improving both the quality of, and the speed with which, information flowed between the institutional and the systems level within the Nation’s provision of higher education. The immediate purpose of what was to become higher education’s ‘new instrumentality’ was not to lay down principles for a new relationship between government and higher education. Rather, its purpose was conceived in terms of updating and making the existing relationship more efficient – an efficiency operationalized primarily in terms of budgetary compression, with new parameters for the usage of academic resources. One of the more spectacular of these latter was the readiness of central authorities to let the staff/ student ratio float as the student wave engulfed higher education whilst imposing a policy of ‘no growth’ upon the size of the Academic Estate.

What then altered thinking about the place of performance indicators? Where are the origins of that new, powerful and highly sophisticated instrumentality which, in its early stages, was heralded by many students of higher education as a new relationship between government, higher education and society, a relationship based on the notion variously qualified as ‘remote steering’, ‘a facilitatory relationship’? (Neave & van Vught, 1994; van Vught, 1989) This is important to understanding the driving forces that changed an administrative procedure into a full-blown theory, which redefined both the operational dimension itself and changed radically what was held to be the ‘proper and effective relationship’ of higher education with society.

Two Schools of Thought

The first of these driving forces may be cast as ideological, though often presented in a technical discourse. It turned around the conviction amongst national authorities that the Guardian relationship – which had determined the historical and political ties between State and higher education for over a century – was no longer sustainable in its present form³. To this line of argument were several strands best summarized in terms of two dis-

tinct approaches. The first focused primarily around a discourse where the Economic imperative predominated (Dill *et al.*, 2004). Its heartland – at least up to 1989 and the fall of the Berlin Wall – lay in the United Kingdom and the Netherlands. In terms of economic doctrine, it may be variously qualified as ‘neo-liberalism’, or when applied to the purpose and relationship between higher education and society, it assumes the trappings of the ‘productivist thesis’. Both strands assigned a fundamental redefinition to operational efficiency. Operational efficiency was no longer conceived as a subset within the established relationship of government, higher education and society. On the contrary, under the canons of neo-liberalism, operational efficiency became the essential credo, the singular, central purpose and objective – and let it be said, the main lever – that opened the way to root and branch ‘re-engineering’ of the higher education system *in toto*. From a historian’s standpoint, it brought the Guardian relationship between government and higher education to an abrupt end and that, as the sinister expression has it, ‘with extreme prejudice’. In effect, the ‘operational’ became ‘the political’.

There is, however, a second school of thought. It too also performed sterling service in shaping the rise of the Evaluative State in Western Europe. It too was no less political. Its focus, however, was very different. Its roots are to be found less in an economic discourse – though obviously this element was not absent. Rather its origins lie within the domain of participant democracy and, more to the point, related to the consequences that social change and enhanced participation in higher education held for the place, identity and responsibility of communities other than the Nation State in the affairs of higher education. Under this setting, operational efficiency took on very different overtones. Whilst it did not deny the desirability of institutional accountability and the other elements of closer financial scrutiny, these were neither its alpha nor its omega. To use a theory less current at the time than it is today, the second school of thought revolved around the principle later to be known in EU circles as subsidiarity – that is the delegation of responsibility to the point where services are provided (de Groof, 1994).

Seen in these terms, operational efficiency took the form of reassigning elements of control and responsibility from central national administration and their relocation, sometimes in the purlieu of regional authorities, sometimes reassigning them back to the individual establishment. This parallel process parades under many flags: ‘the Offloading State’ when seen from a perspective of national administration, ‘the repatriation’ of functions when viewed historically and from the standpoint of the region or the individual institution (Neave, 2001, 2003). Seen within the perspective of politics, it corresponds to the classic and routine notions of administrative decentralization and the devolution of power. This dimension in the rise of the Evaluative State was particularly marked in France, Spain and Italy. It accompanied the federalization of Belgium in 1988 and the splitting of a hitherto national system of higher education into two linguistic communities – one Flemish-speaking and the other French-speaking. Each of the Belgian community developed its very specific institutional form of evaluation policy (Lub, 2003: 5) This was also the route followed by the 13 Spanish Autonomous Communities (Miguel Diaz, 1999) and forms a *leitmotif* in Swedish higher education policy (Bauer, 1988; Bauer and Kogan 1997). Interestingly, the one exception to the federal model is to be seen in Germany. There, though reform to institutional funding, autonomy and the introduction of the principle of contractualization took place

during the latter half of the 1990s, it resulted not in strengthening the apparatus of the Evaluative State at federal level so much as its fragmentation between each of the individual Länder. Paradoxically, the rise of the Evaluative State in Germany was not accompanied by the Central State acquiring further leverage. And to this extent, the Evaluative State in Germany took root *within* the traditional administrative framework between provinces and central government, rather than altering it (Kehm & Lanzendorff, 2006).

Roads to Rome

Regardless of whether the rationale of the Evaluative State obeyed the canons of neo-liberalism or adhered to the imperatives of participant democracy, irrespective of whether the emphasis lay on reasserting the ‘rights of the individual’ to ‘consume higher education’ or, on the contrary focused on the no less indisputable rights of historic and linguistic communities to have greater sway over the institution that intimately shaped both regional identity and regional fortunes, each posed a direct challenge to the place of the central State in the affairs of higher education. Interestingly, both schools of thought shared a common presumption, even if the remedies they advanced differed radically. Both concurred with the desirability of limiting the power of central government. For the theorists of neo-liberalism, the state as regulator was replaced with the notion of ‘market forces’ as the prime regulator of system development. For the supporters of ‘communitarism’ the main burden of change called for a redefinition of the administrative relationship of higher education and government along the lines of a shared partnership between central government and regional authorities – in effect, strengthening the intermediary level between national administration and individual university. Or, as we have seen in the case of Germany, the preservation of the cultural sovereignty the Länder had long possessed. There are, in short, many roads and many justificatory routes that lead on to the Evaluative State.

Leaving aside a more detailed analysis of which higher education system took which pathway to the salvation the Evaluative State held out, let us simply note the amazing dynamic the Evaluative State displayed in Europe. One gains some impression of this dynamism when account is taken of the number of national systems, which moved towards a formal evaluation system in its modern sense. The first step along this road was taken in 1985, with the creation of the French National Evaluation Committee (Staropoli, 1987). By the summer of 2002 within the 30 odd national systems of higher education that formed part of the European Network of Quality Assurance Agencies, created in Finland in 1998, some 34 agencies were given over to Evaluation and Accreditation (Schwartz-Hahn & Westerheijden, 2004).

The Evaluative State and Legal Homogeneity

Irrespective of the particular discourse that accompanied the evolving Evaluative State, whether justified in terms of neo-liberalism or participant democracy, the functions of oversight and the assessment of institutional performance were not the only ones to

undergo marked change. Also to the fore was what some students of higher education policy have termed ‘Legal Homogeneity’ (Neave & van Vught, 1994).

The concept of Legal Homogeneity may be seen as the prime legal construct that governed the relationship between higher education and society, and very particularly so in the historically large systems of Western Europe – Germany, France, Spain, Italy, and at a less exalted level, the Netherlands and Sweden. Legal homogeneity upheld a number of powerful legal fictions, which are not shared by the Anglo-Saxon systems of higher education and thus may be seen as features of essential difference (Neave, 2001). Prime amongst them is the notion that all public universities are on a footing of legal equality and thus have similar status. The second is no less significant. It largely determined the way systems adjusted to change, an adjustment registered in formal, legal enactment which, worked out by central authority, applied homogeneously across a given sector of higher education – universities, short-cycle higher vocational establishments, etc.

Legal homogeneity also determined the nature of system change by linking it indissolubly to the political process at the national level, often requiring full debate in the National Assembly, or its equivalent. To this should be added a further detail: system adjustment rested on the presumption that change, when finally legislated, was introduced in a uniform manner across the appropriate sector. The principle of legal homogeneity emerged at its most visible and powerful in such areas as the conditions of individual access to higher education, the structure, titles and privileges attached to officially certified knowledge that universities awarded in the name of the State, conditions of academic employment, career and promotion. In effect, precisely because of the very principle of legal homogeneity, change involved both heavy formal procedures, often greatly time-consuming, legislative enactment and for that self-same reason tended to be highly politicized.

It is not coincidental that it should be France – a nation where legal homogeneity stood as part of the revolutionary tradition of equality before the law – which established the first of the modern institutions of evolution and oversight, largely in an effort to break out of political deadlock that had long beset higher education policy. No less important was its parallel objective – to put in place a mechanism of review and assessment with the purpose of strengthening institutional capacity for self-determined innovation and initiative. In short, the purpose of Evaluative State *à la française* was to attenuate the rigidity of legal homogeneity by encouraging the Academic Estate to develop a proactive capacity and initiative in developing and shaping the individual establishment, rather than looking to central government or to the Ministry. In the French context, the purpose of institutional evaluation was to provide a map, regularly updated which furnished a synoptic statement of the development and performance of the higher education system, a map that showed the place the individual university occupied in the national system, the better to base institutional initiatives on clear, pragmatic and comparable information. (Neave, 1996)

Evaluatory Homogeneity: A Powerful Lever

The Evaluative State was set in place to speed up, facilitate and lighten the complexities of reform at the level of the individual institution. Yet, the price of its advance involved the deliberate fragmentation of earlier procedures that had accumulated

around legal homogeneity. This it did through various initiatives – through delegation of responsibility – sometimes presented in terms of ‘strengthening institutional leadership’ – through enlarging the activities that individual universities could determine on their own – which is also presented under the rubric of the managerial revolution in higher education, or as extending the canons of what is termed as the ‘New Public Management’ (Pollitt, 2002). By so doing, the Evaluative State also involved redefining the notion of homogeneity. More significantly such a redefinition shifted the concept of homogeneity from its legal *habitus* into the operational domain of the evaluation process itself.

Legal homogeneity thus migrated towards the operational domain and evolved into evaluatory homogeneity – a homogeneity explicitly and deliberately upheld by formal and rigorous procedures of auditing, located sometimes as a separate service within the organization entrusted with the task of evaluation and assessment – which is the model found for instance in England and Sweden – or sometimes handed off to a separate body; for example, to the Inspectorate of Higher Education in the Netherlands (Scheele *et al.*, 1998; Jeliaskova & Westerheijden, 2002) and France (Neave, 1996).

Evaluatory homogeneity – which may be seen as a complicated way of describing ‘bench-marking’ – that is, the setting of minimum targets of achievement and productivity – is an extremely potent construct within an instrumentality of assessment, evaluation and verification already powerful. Indeed, a very good case can be made for seeing the principle of homogeneity operationalized through review and assessment as more pervasive, penetrating and effective by far than its legal counterpart could ever have dreamt of. Powerful and sensitive on its own account, evaluatory homogeneity becomes a force to be reckoned with when taken in conjunction with other developments and very particularly so when one attends to changes in university funding systems.

Conditional Financing: Prime Instrument of Leverage in the Evaluative State

That public sector higher education is today expected to compete for private resources comes as part of that fundamental change in mentality, which the Evaluative State was designed to bring about. Higher Education is no longer viewed as being wholly a public good. Not surprisingly, the quest for resources other than from the public purse received no small urging by governments and Ministry, though obviously the degree of pressure brought to bear and the means by which it was brought to bear, are legion depending on the state of national wealth and hellfare! Amongst the more obvious forms of leveraging policy in Western Europe have been the introduction of ‘conditional financing’, the establishment of a contractual and continually renewable and therefore negotiable relationship between central government – and in certain instances such as France, Spain and Italy – between regional government and the individual university. And whilst few if any systems of higher education have gone so far down the road as the British by directly tying institutional performance to finance, the implicit association between one and the other is clear for all to see. What enhanced

the leverage that evaluation could exercise, however, came in the shape of a *posteriori* financing – that is, funding by output rather than as had previously been the predominant practice, funding on the basis of input – mainly related to student numbers. That funding higher education now focuses on the same area as evaluation – both concentrate on institutional output as the supreme criterion for assessing performance, measuring productivity and institutional output – must surely be one of the most telling factors in shaping institutional behaviour.

This in turn raises a number of questions. How influential is the Evaluative State? In what way does its operational core differ from the legally based instrumentality that preceded it?

The Power and the Potency of the Evaluative State

With higher education policy largely dominated today by the economic perspective, which naturally places weight upon resources, their origins, their generation, their usage and, last of all, what that usage achieves, older and more classic perspectives tend to go by the board. The questions of power, authority, who wields it and to whose benefit it is wielded tend to take a back seat before dissecting out and verifying the technical effectiveness and methodological validity of new procedures and criteria of assessment that by their very nature are precise and lend themselves to both evaluation and sometimes literally to satisfying reward. Furthermore, policy research, as it takes on greater precision also acquires a deeper technicity often at the price of a concomitant and distressing narrowness (Neave, 2004a). As a result, we are well able to count the leaves on the branch, even distinguish their hue and shape, but we tend to have lost any grasp over the state of the forest, let alone its topography and its extent. To this general proposition, the Evaluative State is no exception.

The Evaluative State is about verifying performance, about tracking – the world-weary might say, racking up academic productivity – whether construed in terms of students graduating within the legal time limit, the number of PhDs produced in areas deemed relevant to the Nation's future (Lindqvist, 2006), refereed publications, patents taken out or splendidly enormous contracts signed with firms prominent in the Fortune 500. The Evaluative State is an agent for verifying efficiency and thus many of the studies that have been made of it, tend in the same direction. They tend to eschew the question: 'What is the basis of power that makes the Evaluative State so potent?'

Perhaps such delicacy and discretion simply reflect that at one level the answer stares us in the face. The Evaluative State is powerful precisely because its function is to verify the take-up of policy. It is the agent whose prime purpose is to ascertain implementation on the one hand, and on the other to make sure the individual university, *Fachhochschule*, *Institut Universitaire de Technologie* and polytechnic, upholds its commitment to the thrust of public policy. In other words, the Evaluative State is concerned with the capacity – whether at system, regional or institutional level – to sustain policy goals and, at the same time to ascertain an institution's capacity to adapt where necessary. Graphically put, in these latter days, for the university world the Evaluative State fulfils a function very similar to the Holy Office in days long gone.

Institutional evaluation serves to remind the laggardly of the horrid consequences of persistent sinning. Its theology finds a counterpart in the rigours and orthodoxies of economic efficiency. The Evaluative State is powerful by the nature of the information gathered and by the degree to which that information lends itself to disaggregation, to re-aggregation across different operational levels from base unit, to institution and on to systems level. Any oversight that at one and the same time allows comparison between individual institutions – even individual disciplines – and also permits re-aggregation into regional, provincial and national level cannot be entirely weak, though over time its effectiveness can be eroded and sometimes even blunted (Huitema *et al.*, 2004; Scheele *et al.*, 1998; Jeliaskova & Westerheijden, 2002; Neave, 2006b).

‘Academic Time Versus Productive Time’: A Very Long Perspective

These are the more obvious forms of power the Evaluative State wields. There are others. They have direct consequence for the evolving relationship between higher education, government and society. Indeed, they flow directly from setting up the Evaluative State itself. The first of these is commonly alluded to as ‘productivism’ – that is, the direct harnessing and application of university production to economic purpose, which may also be national purpose as well. There is, however, another aspect to ‘productivism’. It relates to the notion of ‘academic time’, which has been central to the way the university has functioned for a very long time indeed.

For the best part of nine centuries, the one element over which academia had great if not total mastery was precisely over time – time to teach, to learn and to acquire knowledge. To be sure, universities tend no longer to consider their mission ‘*sub specie aeternitatis*’. Nevertheless, the days are not too distant when the pursuit of higher learning was still possible without major research grants simply because the prime value – time itself – was academia’s principal and unique capital. That is what tenure and its granting are all about – the pursuit for knowledge irrespective of the time it might take.

The command of time was the essence of academic freedom, even in the days when knowledge itself was revealed rather than scientific (Neave, 2006a). Evaluation and assessment regularly undertaken as a national exercise are in effect the essential lever to ensure that ‘academic time’ mutates into, and is replaced by, ‘productive time’. For in truth, even if this consequence is nowhere written explicitly into the list of objectives that are assigned to such agencies of Quality Assessment, Accreditation, Audit or Public Accounts that are variously associated with regular scrutiny of institutional performance, this shift nevertheless had taken place. To be sure, there are various technocratic terms that disguise the unpalatable reality – ‘time budgeting’ is one, ‘speeding up institutional response’ another. But this is merely a linguistic sleight of hand that in no way undermines the essential truth that the conversion of academic time into ‘productive time’ is a salient, silent and hugely significant trend in present-day higher education policy. As an aside, the use of such terms as ‘time-budgeting’ is itself redolent of the deepening technicity and linguistic alienation in policy research alluded to earlier.

The Externalization of Academic Norms and Functions

Changing academic time to productive time stands at the intersection of a number of separate processes all of which involve fundamentally redefining both university identity and hence its relationship with society. The introduction of ‘productive time’ into the groves of academe can of course be justified as a necessary development and very particularly so when change is held to be continuous rather than as a stop/go process. In the second place, it may also be seen as part of that process of ‘incorporation’ which in turn has two meanings: the taking over of corporate business practices, forms of organization, job description, hierarchy and very often conditions of service (de Weert & Enders, 2004); second, the redefinition of the university no longer as a unique organization – with a unique task – so much as one subset in a broader series of linkages sometimes qualified as the ‘innovation system’ (Neave, 2006b).

These developments, disparate though they might appear, nevertheless possess a common thrust, namely the subordination of long-held university norms and their realignment upon external practice – a trend that reaches its fullest expression in the notion of competition itself. Competition has never been absent from the university. On the contrary, as the American sociologist, Burton R. Clark pointed out nigh on a quarter of a century ago, competition is the central currency of academia – the gold coin of exchange, repute, standing and excellence (Clark, 1983). And this latter perspective gives us a further clue to the power of the Evaluative State.

An Operational Core More Sophisticated

If we scrutinize the central core in the Evaluative State’s operational domain, we see that academic time is not the only condition to have changed. There are others and they have a strange odour of expropriation. For if the Evaluative State confirms a mutation and change in the referential norms that now shape the higher education enterprise, it has also taken over to its own account and to its own particular ends two other instruments that are equally vital in shaping what another American policy analyst, Martin Trow, termed the ‘private life of academia’ (Trow, 1975). The most telling addition to the leverage – and thus the influence – the Evaluative State can exercise over academia has been the addition to its operational armoury of competition and peer review. The use of peer review – quite apart from the derivatives that the Lords of Evaluation may devise in their own interest, ‘guided’ ‘focused’ peer review, for instance – (El Khawas, 1992) – is a clear example of that broader process, central to constructing the Evaluative State – namely the externalization of practices previously internal to academia and their application to the business of assessment and verification.

Whether such additions to the central operational core of the Evaluative State illustrate the process of ‘externalizing’ the practices that previously characterized the University’s private life (Kogan, 2006) or whether they are simply presented as elements central to installing a new transparency in tracking the dynamics of higher education development, it is, I think, undeniable that both interpretations provide a very substantial pointer to the high sophistication of the instrumentality the Evaluative State now commands.

Institutional Image: Creation, Destruction and Impact

There remains one last area where the Evaluative State wields much influence. This concerns what is best described as the ‘individual university’s image’. I say ‘would appear’ because to the best of my knowledge the question of the impact of evaluation upon the standing a university might have amongst the public has yet to be tackled. Yet the question of image is important, both in the setting of the Evaluative State and more so as part of the policy of ‘marketing’ higher education. Whether the key product of the Evaluative State – league tables of ranking as a result of assessment – effectively *do* influence student choice is not in itself important. What *is* important is that institutions and their leadership *appear to believe* they do. More to the point, though this is not yet a universal trend, institutions set about capitalizing on favourable results or limiting damage if performance has not been up to their own expectations.

Thus, the Evaluative State plays a crucial role in the area of institutional image-building. Indeed, the more higher education is construed as a ‘marketable product’, the greater the influence must accrue around any agency that has the express purpose to define a university’s public image which, *soit dit en passant* is not necessarily always the same in academia as it is to the parent in the street, even though the purpose of the Evaluative State is to ensure that as far as possible, they coincide. The Evaluative State provides the basic material for the public’s perception of both the higher education system and the individual universities within it. Expressed in the hackneyed language that all too often belittles the art of journalism, the Evaluative State is wholeheartedly engaged in ‘putting an end to the ivory tower’. To traduce the expression of the father of Sociology, Max Weber, the task of the Evaluative State is to ensure that the university is both ‘*in* the world and *of* it’.

From a different angle, but no less significant, it is at this point that institutional performance becomes the handmaiden of competition with the one reinforcing the other. Thus, the power of the Evaluative State resides in the images it allows to be built of the higher education system it evaluates. However, image-building is yet another instance amongst the many we have already noted of that process analysed earlier in the context of ‘the displacement of functions’. Here, however, it involves modifying and relocating the hitherto closed cycle of reporting and accounting, which in that earlier mode of system coordination identified with Legal Homogeneity, took place exclusively – and very often privately – between university leadership and national authorities. It brings that cycle into the public domain.

Exporting the Evaluative State

Earlier in this chapter it was argued that the Evaluative State represents a transition inasmuch as policymaking in higher education thereafter rapidly took on a European dimension. And whilst the coincidence in the timing as individual Nations began to put the structures of the Evaluative State in place may also be interpreted as ‘policy convergence’ within a Nation State setting and with individual Nations acting independently to meet change unceasing, so there is sufficient evidence of another phenomenon that

anticipated if it did not directly give further weight to the supranational aspect. In the inimitable jargon of the Brussels bureaucracy, this involves the principle of ‘portability’ – that is, the take up and application of a policy devised by one system of higher education by another. There are, not surprisingly, other descriptions: in the classic vocabulary of comparative education it parades under the flag of ‘borrowing’.

It should not be thought, however, that ‘portability’ is a development found only in Old Europe, though the rise of the Evaluative State – above all after 1991 – saw an intense activity on the part of the ‘pioneering’ Nations to export their particular versions of it. Thus, we find France advising authorities in Italy, Spain, and Portugal, and the Netherlands active in making its experience in the area of performance indicators and quality assurance procedures available to the Czech Republic, Slovenia, Hungary, Poland and Russia.⁴ Then, there are the British who give advice on evaluative techniques to everyone and the Swedes who give advice to none since they are taken up with shaping their own radical edition of the Evaluative State, based on a series of assumptions and purposes very different from the rest of Europe (HSV Rapport, 2005). Interesting and indeed vital though this example of ‘cross-frontier exchange’ and portability of policy very certainly is in moving the governing principles of higher education policy from Legal Homogeneity to Evaluative Homogeneity, it responded to very different needs in the ‘New Europe’.

Inside, Outside

To newly liberated countries, struggling to reach some measure of order and stability in the relationship between government and higher education, the strengthening profile of the Evaluative State in Old Europe was not a matter of polite interest alone. As Old Europe multiplied the numbers of agencies involved in overseeing Quality Assurance and as the procedures to review, visit, monitor and assess both institutions and systems became institutionally embedded features, so close scrutiny from the New Europe grew (Tomusk, 2006). The extension of Evaluatory Homogeneity to include the central issue of accreditation – the assessment and validation of institutional fitness to develop new programmes, degrees and qualifications – merely concentrated interest further. Several motives were at play. In the first place, the development of quality assurance, evaluation and accreditation structures were seen by the newly independent lands as key and quintessential features in what they held to be – and indeed often described in their official publications as – ‘the European system of higher education’.

The very idea of a ‘European’ system was premature. Indeed, the notion itself received little sympathetic hearing from precisely those engaged in substituting Legal Homogeneity with Evaluatory Homogeneity in Western Europe. Important though the quest for quality and access to accreditation both were to those Nations in Old Europe actively engaged in their development, neither was regarded as a major identifying feature in any system, let alone a *European* system, the idea of which was at the very best but a single dimension in the complexities of higher education policy, still largely conceived in terms of individual Nation States (Neave, 2001). Yet the persistent allusion by authorities in the newly liberated lands to a ‘European higher education system’,

grossly inaccurate and thoroughly eschatological though it was, had a purpose. That purpose was for internal consumption only and destined for the home front.

Vision and Purpose: The Solution to the Crisis of Legitimacy

In the ‘New Europe’, the vision of a ‘European system’ of higher education provided an example and a goal for national purpose. This it did – not simply by focusing attention in the higher education community back home upon the issue of European integration (Tomusk, 2006). By associating Quality Assurance and Accreditation with a ‘European system’, however mythical it might appear to outside observers, authorities in the ‘New’ Europe could justify establishing similar agencies of control, with similar functions and often similar titles, irrespective of the nature of the system – private or public. The re-establishment of control was thus legitimated. This was not state bureaucracy resuscitated or the resuscitation of Stalin’s ghost. On the contrary, the taking on board of both Quality Assurance and Accreditation, the measures to set them in legislation derived from a new legitimacy – which operated on two levels. These two levels were: first, that the policy of legislating the status of the private sector was not to bring it to heel or to constrain it.⁵ Rather it formed part of an overall strategy to bring the national system of higher education up to a modicum of formal organization and administrative harmony that could sustain competition and the possible challenges of European integration, when the time came. Second, the legislative enactments this required were far from reverting to an earlier administrative homogeneity through legislation. They were, on the contrary, the necessary preliminary to the establishment of these mechanisms and procedures to bring the national system into line with the most recent policy in Western Europe. Far from being a step backwards, legislating a framework of Evaluatory Homogeneity in New Europe served as a clear sign of the wish by governments to be seen as part of the ‘European’ system they professed to see.

Envoi

In this essay, I have examined changes in the relationship between higher education and government in Europe, West and East. I have focused on the rise of the Evaluative State. In both the ‘Old’ Europe and the ‘New’, though for reasons very different in each case, the Evaluative State is a powerful policy construct, though the role it played, just as the policies it advanced, were also radically different in each. Whether these differences will move on towards a common vision is a matter that only time, political intent and sheer institutional capacity to endorse that vision will tell.

In tracking the rise of the Evaluative State, I have also sought to dissect the basis of its power. It is considerable. Its instrumentality is deeply penetrative into the lives of individual institutions. In certain countries, it is deeply penetrative into the lives of individuals too. Yet, it is also subtle and sophisticated. In effect, the instrumentality of institutional evaluation and assessment moves the discourse that surrounds the notion of ‘remote steering’ onto a different plane. The Evaluative State works through assessing institutional output. Whilst it still remains the case that very few Nations tie public

funding directly to performance, from the standpoint of the leverage evaluation has upon institutional behaviour and leadership's perception of institutional repute and excellence, it is arguable that close ties are not necessary – at the moment. They may be later, however (Jeliaskova & Westerheijden, 2002).

The heart of the system of leverage –if leverage may be said to have such an organ – resides in the Evaluative State conveying its results publicly so they are available to all stakeholders. It acts directly on institutional repute and claims to excellence. It verifies on a regular basis the quality of the services provided by institutions of higher education. If the truth were out, the Evaluative State, acting directly through agency evaluation and agency oversight gives a new reality to the notion of 'remote steering'. By so doing, it raises the question whether the claim of political authorities to have reduced the power of the State is reflected in reality, in face of a rhetoric which is as pervasive as it is so often at odds with that reality (Neave, 2004b).

One of the more important changes the Evaluative State has brought about is the replacement of what is sometimes known as 'Legal Homogeneity' as one of the central principles that shape the relationship between higher education and government. In the Evaluative State, Legal Homogeneity, yields before the notion of 'Evaluatory Homogeneity'. It is a change of major import if only for the fact that ostensibly it pays scant attention to the classic issue of public versus private in the Nation's provision of higher education. When the judgement of institutions is made on the basis of their output, it really does not matter a fig what the form of ownership takes. Still, ownership may be relevant when we seek to explain outstanding achievement – whether for better or for worse. That, however, is a different kettle of fish.

The Evaluative State, I would suggest, brings the debate in higher education to other pastures. It moves debate on, for instance, to the impact and consequences the Evaluative State has upon the emergence of new forms of institutional differentiation as institutional leadership responds to the perceived standing – or ignominy – that public evaluation lays upon the individual institution. Since one of the elements in public policy that has marched in step with the rise of the Evaluative State has been the extension of the scope of institutional self-government, the interaction between evaluated status and institutional behaviour becomes a matter of the utmost interest – and relevance! Evaluatory homogeneity shares a common point with Animal Farm. As Mr Blair – Eric not Tony – had Napoleon the Pig point out to his stalwarts 'All Animals are equal, but some are more equal than others.' Whether universities are more equal or less is, of course, the duty of the Evaluative State to find out! The shame or fame are matters for consumers and stakeholders to judge (Neave, 2002).

In effect, the Evaluative State returns us to the fundamental issues of power, authority and above all, the ends to which the Evaluative State is set to work and to service. It does so paradoxically because the Evaluative State itself is focused largely on means. Efficiency is a means in search of an end. And what is justified in the name of efficiency can be – as in a not too distant past, it has indeed been – used to uphold social constructs of the most dubious sort. The Evaluative State then brings us back to the basic and abiding questions that society has always to pose to itself. It does so because the overall – and perhaps artificially coherent – vision of higher education that Legal Homogeneity once provided is dissolving. With individual institutions of

higher education using the greater latitude officialdom has granted to shape their own particular profile and mission, coherence wavers before the prospect of fragmentation. The technicity of the Evaluative State, its sophistication and methodological nicety ought not to blind us to the fact that performance is important. So is coherent purpose. With an instrumentality more effective in shaping institutional behaviour than ever before, the central questions remain: Higher Education for whom? On whose terms? To advance what type of society? And to realize what social vision?

Notes

1. The latter aspect was of particular concern to the Dutch authorities for whom the solution lay primarily in terms of the Division of Tasks and the Concentration of higher education.
2. Chronologically, reductions in university expenditure began in 1981 in the UK and the Netherlands, in 1986 with the Santa Anna Plan in Belgium
3. Others may see it in terms of the Humboldtian Concordat between State and University in which the former guaranteed the intellectual independence of individual scholars grouped within that corporation and which took the operational form of a State monopoly over the financing of the public sector as part of the national heritage and achievement. (For this see Neave *et al.*, 2006)
4. Though by no manner of means alone in this undertaking, the Centre for Higher Education Policy at the University of Twente has been closely involved in providing the technical input both to intergovernmental exchanges as well as training Ministry officials from East and Central Europe in the arcana of the evaluative state, quality assurance, evaluation and accreditation for the past 15 years.
5. This was not always born out later. For instance, whilst the Russian Law of 1992 recognized the right to establish higher education on religious or corporate basis, and was thus relatively accommodating, its successor in 1996 began to apply accreditation procedures to separate sheep from goats in the private sector. Some have interpreted this as bid by the Old Guard in Ministries to protect the State sector (Tomusk, 2005). Whilst this might well be so, there is little point in putting in place accreditation systems à l'occidentale if they are deprived of judgemental teeth. Besides, the new theology recognizes that such rigour can always be justified in the name of consumer protection (Ovodenko, 2004; Smale and Gounko, 2006).

FROM COHERENCE TO DIFFERENTIATION: UNDERSTANDING (CHANGES IN) THE EUROPEAN AREA FOR HIGHER EDUCATION AND RESEARCH

Wim Weymans

Introduction

It would be no exaggeration to say that the aim of a European research and higher education policy is the creation of a ‘European research area’ (ERA) or a ‘European area of higher education’ (EAHE). Although people in the field may be more affected by, and thus acquainted with, the process of European higher education reform known as ‘Bologna’, the aim that underpins this process is the construction of a common area for higher education. Particularly since the intergovernmental agreement in 1999, known as the Bologna declaration, and the European Commission’s initiative in 2000 to make Europe the world’s most competitive knowledge-based economy, known as the Lisbon Agenda, the formation of this area by 2010 has been high on the European agenda. There is a marked contrast, however, between the pervasiveness of this concept of a European area and its lack of conceptual clarity. What, then, do people mean when they refer to such a European area?

This chapter will argue, firstly, that one can discern at least three different ways in which the European area for research and higher education is understood and structured: while referring to the same area, people often mean different things by it. This chapter will also show who defends which space and how different groups wish to govern it. Although it will mainly focus on the Commission’s discourse on universities, it will also take into account other voices.

Second, this chapter will argue that over the past few years, one can witness a dramatic and paradigmatic shift in the way this area is understood and structured. One can describe this shift as the evolution from a model of coherence and cohesion towards one of differentiation or competition. While the model of coherence stresses and creates similarities between different European universities, the new model focuses more on differentiation. Interestingly, this change affects all three conflicting views mentioned before. The chapter then examines how, as a result of these changes, the financial and political stakes of the European education and research area are getting higher. I shall also show how this new paradigm produces new agents, a new rhetoric and new modes of governance.

Despite its importance in terms of budget and strategic impact, very few EU scholars devote attention to research and education policy: for example, in Wallace *et al.*,

2005 there is no chapter on this topic. While there are many interesting books on the idea of a ‘European space’ (Jensen & Richardson, 2004), on the construction of a European identity (Shore, 2000) and on the relationship between a European space and that identity (McNeill, 2004), very little attention has so far been devoted to the area for research and education. True, some researchers have started to investigate the European area of higher education (van der Wende, 2001; Nóvoa & Lawn, 2002; de Wit, 2003; Keeling, 2004). Yet most of these existing studies examine the area of higher education and that of research separately, thus simply duplicating the bureaucratic division of labour between the respective European Commission’s directorates-general of education (DG EAC) and research (DG RTD). By contrast, this chapter takes the higher education and research areas together. This is because universities are characterised by precisely the combination of education and research, which means that changes in education affect a university’s research and vice versa. The fact that the Bologna process – which traditionally only touched education – currently also reforms doctoral research (The European Ministers of Education, 2005: 3–4) shows how artificial this distinction has become. Similarly, the Commission’s power, which was initially mainly limited to research, has now *de facto* expanded to higher education policy as well (Keeling, 2006). This explains why stakeholders ask that “these two policy agendas urgently need to be viewed together” (EUA, 2005: 3). Taking them together may allow people to see the massive nature of the changes that are underway.

Fighting Over European Areas for Higher Education and Research

What is a European area for higher education and research? The trivial answer is that it is simply a geographical area in which there are about “4 000 institutions, over 17 million students and some 1.5 million staff – of whom 435 000 are researchers” (CEC, 2006b: 3, 2003: 5).¹ In this sense, a ‘European university’ is a university located in Europe, just as a European city is a city that can be found on the European map. However, for most people agents the mere presence of institutes of higher education in the same geographical space is, in itself, not enough. Indeed, nothing guarantees that these institutions know about each other, understand each other’s systems or exchange information. When European ministers of education began with the ‘creation of the European area of higher education’ in Bologna in 1999 and the Commission 1 year later had the idea “to create a European research area” (CEC, 2000: 8), they meant more than just geography. In order to feel part of a larger area beyond the borders of the region or the nation state, one should not simply be objectively on the European map, but also be subjectively connected with other people. Creating a European area means that existing institutions at least know that they are part of the same space or landscape and feel connected to each other. How can this be achieved?

I believe that, until recently, for most people the answer to that question lay in increasing the coherence and cohesion of standards and degrees. In European jargon this cohesion is often also referred to as ‘convergence’ (in the field of education) or ‘harmonisation’ (when talking about research) and one could also use terms like

‘standardisation’ or ‘coordination’. Given the consensus on this answer one can see it as a paradigm, that is to say an ‘entire constellation of beliefs, values, techniques, and so on shared by the members of a given community’ (Kuhn, 1996: 175). Such a model or paradigm is of course an abstract ideal-typical construct, which therefore leaves room for different appropriations. I believe that in policy documents and initiatives one can indeed discern at least three different ways of conceptualising and constructing such an area according to the model of coherence. As we shall see these views also differ on the question of who should ‘govern’ this area (Treib *et al.*, 2005).

A first way to turn a European map into a European area through coherence is obviously to create common or shared standards and points of reference. In this sense universities can only be called European universities if they share the same degrees, standards, credit systems, indicators and infrastructures. Once they do this, universities will start comparing themselves with other European universities rather than merely with universities in their own country. Moreover, once they share the same standards and degrees, they will become readable and visible (and therefore accessible) for insiders and for outsiders. By way of comparison one can say that many European cities are ‘European’ because they share for example the same currency or traffic road system, which gives them a distinct European dimension beyond their typical features.

This first attempt to create a shared European space through sharing standards clearly underpins the Bologna process that aims at a further achievement of ‘greater compatibility and comparability’ of the systems of higher education (The European Ministers of Education, 1999) through the ‘adoption of a system of easily readable and comparable degrees’ that provides ‘a common reference’ (CEC, 2005: 6). The aim then was to ‘strengthen the convergence of higher education systems’ (CEC, 2003: 4), notably through the creation of a European Qualifications Network, ‘commonly accepted guidelines and criteria’, a shared quality assurance and a European credit transfer system (ECTS) (The European Ministers of Education, 1999, 2005, 2007; CEC, 2005: 6–7, 11).

The creation of the European research area is equally driven by the need for ‘common references and basic standards’ (CEC, 2005: 6) and the establishment of ‘a common system of reference... by aligning methods, harmonising procedures and comparing results’ resulting in ‘the development of a European scientific and technical reference area’ (CEC, 2000: 15). To that aim ‘the collection of data throughout the Union... needs to be improved and statistics and indicators developed at European level’ (CEC, 2000: 20). As in the economic free market, in the market of research too, the aim is ‘to simplify and harmonise regulations and administrative conditions’ (CEC, 2000: 19).

In short, students and researchers alike should be able to refer to a shared European horizon, expressed in similar degrees and comparable scientific indicators. As the Bologna process has shown, to realise this first spatial vision, ‘soft’ or minimal modes of governance (like the ‘open method of coordination’) involving national ministers and several stakeholders normally suffice, as one does not in principle need a supranational body to coordinate national policies.

Yet, for the European Commission in particular this first answer is insufficient for obtaining a ‘true’ European area. For them, creating a shared space not only presupposes sharing standards but also needs active collaboration through exchange of

students and researchers. Compare this with the idea that truly European cities may be created through collaboration between them, such as partnerships.

This second vision also concretely underpins European policy. In the field of education one can think of the Erasmus exchange programme, which has advanced European student mobility for more than a quarter century. While the introduction of shared degrees affects all students, actual student mobility through Erasmus only involves a relatively small minority (Neave, 2002: 184–185). Consider also the more recent idea of offering ‘more “European” courses, offered jointly by consortia of universities and leading to joint or double degrees at Master or Doctorate level’ (CEC, 2006b: 10). In the field of research there is collaborative research, which aimed at ‘networking of existing centres of excellence’ (CEC, 2000: 8), the creation of networks between different European countries, in order to increase collaboration between different European research teams. In sum, in this view a truly European space only comes into being when universities collaborate through exchange of students or researchers.

More radically still, the Commission supports a third way of developing a European higher education and research area, one that creates new institutions that are detached from existing national territories. As an example of such a truly ‘European’ university, one can think of the European University Institute (EUI) in Florence, where academics and students teach or study after having left their national university. Similarly, consider the creation of a Joint Research Centre (JRC) as an independent ‘European’ research centre, hosted by the European Commission. In the field of research, there is the dream of creating ‘virtual centres’ or ‘real “virtual centres of excellence”’ or ‘real “virtual research institutes”’ through IT tools (CEC, 2000: 8, 10–11). This can be compared with the creation of new capitals (think of Madrid or Brasilia) that are meant to transcend existing regional cities and capitals. The underlying idea here is that a truly European space must be detached from existing places that have a national reputation.

These last two visions imply different modes of governance. Although it would be conceivable that different countries agree to exchange or collaborate (as they often do), it is *de facto* a supranational institution like the European Commission that was able to push through collaboration and exchange programmes on a European scale. Instead of intergovernmental modes of governance, we find here a more centralised way of steering, for example in the field of research where the Commission determines which topics it wants to subsidise. Because of its supranational nature, the creation of new institutions obviously presupposes an even more centralised mode of steering.

Given that the latter two visions of the creation of a European space through collaboration or new institutions presuppose centralised modes of governance, it comes as no surprise that most stakeholders and national governments reject these. The European Commission by contrast emerges as their stubborn defender. Why is this so? The simple answer is that this is because of the Commission’s thirst for power. The more interesting answer is that the Commission’s particular vision of a European area stems from an attachment to a deeply rooted idea that a truly European space should necessarily transcend national institutions and that it involves a detachment from one’s particular national horizon. Just as the Jacobins in revolutionary France saw an opposition between one’s particular background and the true national general spirit, the European

Commission similarly believes that creating Europe involves a detachment from one's national background. Just as French Jacobins created practices and institutions that would actively foster such detachment notably through education (Rosanvallon, 1990: 100 ff), so the European Commission wants to create a European space through programmes of collaboration or by creating new European institutions.

Three Spaces, Two Paradigms: From Coherence to Differentiation

While the fight over these different spatial views continues, I believe that over the last few years the underlying goal and paradigm has changed dramatically. I think that the paradigm of coherence is currently in the process of being replaced by a model of differentiation. Where the final goal of a European research and higher education area initially consisted in stressing and creating similarities between different European universities, more recently the focus has been more on differentiation and competition.²

It was no surprise that coherence precedes differentiation. Both logically and chronologically, differentiation and competition presuppose a minimal degree of standardisation. As the Commission writes: 'a more coherent and compatible European framework... is a condition for the readability, and hence the competitiveness, of European universities' (CEC, 2003: 5; my emphasis). This explains why the Commission, as one of the main advocates of the paradigm of differentiation today, at the same time wants a 'sufficient compatibility between the different national regulations' (CEC, 2005: 6) as a condition for increased differentiation. This also explains why some see the coherence associated with the Bologna process as a tool for a 'badly needed injection of diversity and competition into the European university system' (Lambert & Butler, 2006: 38).

Yet, while differentiation necessarily presupposes coherence, coherence should not necessarily lead to differentiation. While initial standardisation may be a matter of necessity, subsequent differentiation is a matter of political choice and is certainly not a natural evolution. Herein lies the whole political problem. For what is to be done once a minimal degree of coherence is achieved? Should one further distribute funds equally over all European universities to foster further harmonisation, or are shared standards and degrees only a first step to differentiate between strong and weak universities? The answer depends on which model you follow. Those defending the model of coherence will focus on what universities have in common and will want to include all universities. Those who start from the model of differentiation by contrast will focus on differences between universities and will want to foster this differentiation through competition.

To be sure, the *rationale* behind both paradigms was the need for Europe to become a knowledge-based economy. The question had always been are universities 'in a position to compete with the best universities in the world and provide a sustainable level of excellence?' (CEC, 2003: 3, 22). Yet the answers to that question have differed. Those defending coherence believed that international competitiveness would increase through coherence alone (thus making European universities more attractive to foreign

researchers and students) and by distributing more money over all universities. Those aiming at differentiation argued by contrast that coherence alone did not suffice and that differentiation and competition were also needed. Funding, then, should be concentrated on a competitive basis rather than disseminated on the basis of inclusiveness.

According to the Commission, the creation of a true knowledge economy presupposes a concentration of top research in a small number of universities, rather than a distribution of research capacity over as many universities as possible, as the model of coherence would have it. Differentiation thus became the new keyword. While the Commission still said that ‘the aim must be to bring all universities to the peak of their potential’ (CEC, 2003: 16) it also suggested that this potential differed and that a ‘combination of *the absolute need for excellence*, the effects of the precariousness of resources and the pressure of competition, forces universities and member states to *make choices*’ (CEC, 2003: 18; my emphasis). Put another way, the Commission stated that ‘Europe needs universities able to build on their own strengths and *differentiate* their activities on the basis of these strengths’ (CEC, 2006b: 4; my emphasis) arguing that ‘mobilising all Europe’s brain power (...) will require *much more diversity* than hitherto’ (CEC, 2005: 5; my emphasis). The Commission clearly and unambiguously indicated the implications of all this, stating that ‘the *concentration of research funding* on a smaller number of areas and institutions should lead to increased specialisation of the universities, in line with the move currently observed towards a European university area which is *more differentiated*’ (CEC, 2003: 18; my emphasis, see also CEC, 2005: 5). This, then, ‘requires more competition-based funding in research and more output-related funding in education’ (CEC, 2005: 8).

The underlying assumption of the paradigm of differentiation is that in order to be attractive for foreign researchers and students, European universities, like their American counterparts, need ‘the necessary critical mass’ (CEC, 2003: 7). The Commission explains that while the United States, like the European Union, has about 4,000 higher education establishments, only 50 of these ‘account for the lion’s share of American academic research capacity, public funding in support of university research and the country’s Nobel prizes for science’ (CEC, 2003: 5 n.9; CEC, 2006a: 5 n.9). For the Commission, in Europe too a ‘culture of excellence’ can exist only in ‘a few entire universities’ (CEC, 2005: 5). Given that ‘high-tech businesses ... tend to set up near the best-performing universities’ (CEC, 2003: 8), concentration of research is also necessary for technology transfer.

Changing Paradigms, Changing Discourses

Under this new paradigm of differentiation, old words acquired a new meaning. Take the central idea that in order to create ‘a dynamic European landscape’ that is ‘open and attractive’ (CEC, 2000: 18) to researchers, students and investors, both inside and outside Europe, ‘European higher education ... needs to become “*readable*” or ‘*more visible* in the world’ and should be ‘*building an attractive image*’ (CEC, 2005: 4, 2006b: 9–10; my emphasis). With the change of paradigm, the meaning of readability or visibility as central goals of this area changed as well. Under the model of coherence,

increasing visibility or readability only meant making an area intelligible through shared standards and references. The idea was that Europe had a hidden expertise which needed to be made visible or readable to outsiders through a harmonisation of standards and degrees. That was done by ‘mapping’ (existing) European centres of excellence (CEC, 2000: 10).

Under the paradigm of differentiation, readability and visibility now mean making some excellent universities more visible than others through, for example, differentiated funding. Where in the old model visibility simply meant revealing existing excellence by harmonising standards, under the model of differentiation it implies actively creating excellence by concentrating funding in some highly visible excellent universities. Under the model of coherence excellence was deemed to be already there waiting to be discovered, while under the paradigm of differentiation it had to be created. Rather than assuming that Europe already has excellence the Commission now stated that at present ‘most universities... are ill-prepared for worldwide competition’ and that, in the future, ‘Europe simply must have a first-class university system’ or should be ‘achieving world-class quality’ (CEC, 2003: 22; CEC, 2005: 3).

To use the metaphor of light, visibility no longer meant ‘bringing to light’ existing excellence in all European universities by making their degrees readable and comparable, but rather to create excellence by putting the best universities ‘in the spotlight’, while leaving others ‘in the shadows’. The light of coherence is a sun that shines over the entire European stage. Differentiation is a spotlight that picks out the best.

As the meaning of keywords underpinning the discourse changed, so did its basic oppositions. The key dichotomy of the paradigm of harmonisation was between on the one hand a state of ‘fragmentation’, ‘isolation’, ‘compartmentalisation’, ‘disparity’, ‘lack of coordination’ of existing national systems, which needed to be replaced by, on the other hand, ‘de-compartmentalisation’, ‘better integration’ and ‘a more coherent approach’ (CEC, 2000: 7, 9, 18). Under the paradigm of differentiation, that dichotomy is turned upside down: the ideal is now differentiation rather than coherence, which is now opposed to ‘an undesirable degree of *uniformity*’ (CEC, 2006b: 3; my emphasis). The problem is now no longer fragmentation but rather ‘uniformity and egalitarianism’ which excludes those ‘who do not conform to the *standard model*’ leading to ‘an average quality of universities’ and, which is seen in terms of ‘*insufficient differentiation*’ resulting in ‘deficiencies’ (CEC, 2005: 3–4; my emphasis).

Ominously, the Commission openly states that universities should no longer follow traditional models such as ‘the ideal model of university envisaged nearly one century ago [*sic*] by Wilhelm von Humboldt’ because the trend today ‘is away from these models, and *towards greater differentiation*’ (CEC, 2003: 5–6; my emphasis). While it still admits that ‘the link between research and teaching naturally continues to define the ethos of a university... this link is nevertheless not the same in all institutions, for all programmes or for all levels’ (CEC, 2003: 18). Stronger still: ‘while all institutions share certain common values and tasks, not all need the same balance between education and research... research should remain a key task of the systems as a whole, but not necessarily for all institutions’ (CEC, 2006b: 4). A recent report by a European think tank similarly states that ‘there is a growing need for diversity – for some universities with the resources to compete with the best in the

world, and for others to meet regional and local requirements in a first-class fashion' (Lambert & Butler, 2006: 15).

It is hard to tell when exactly the paradigm of coherence was challenged by that of differentiation. In fact, one could even argue that from the very start of the creation of a European area for education and research, the language of differentiation was already present in the documents. Yet, as in the case of visibility, words mean different things here. In the Bologna declaration of 1999, for example, there was already talk about 'increasing the international competitiveness of the European system of higher education'. Yet, this was then interpreted not in terms of increasing competition between European universities, but rather as an argument to boost the competitiveness of all European universities vis-à-vis the United States and Japan. Under the paradigm of differentiation, 'increasing competitiveness' means making the very best competitive at the expense of others. To be competitive with universities outside Europe, then, European universities also need to compete with each other.

The Model of Differentiation in Action

This new model of differentiation is mainly visible in the 'communications' by the Commission, which have propagated it since 2003 (if not earlier). Yet the model was practised in policy initiatives as much as it was preached in those communications. What, then, were the implications of these policy initiatives at different spatial levels?

Let us take the creation of shared standards first. Where, within the paradigm of harmonisation, shared standards were used to enhance coherence between different universities, within the newer model, 'standards' are used to differentiate between them. Consider the creation of instruments for quality assurance, whereby universities evaluate themselves or are evaluated, which fosters competition and differentiation. The Bologna process itself is also affected by the Commission's interference, which leads to 'a growing stratification of the higher education sector in the EU' (Keeling, 2006: 214).

Even more crucially and more significantly at this first level was the creation of a European Research Council (ERC) which is modelled after the National Science Foundation (NSF) in the United States (CEC, 2004). The aim of this ERC is to apply the same standards to all researchers. Yet, the standards are those of excellence rather than the lowest common denominator: 'unlike earlier EU contributions to science funding, it will allocate research grants purely on the basis of peer-reviewed excellence' (Lambert & Butler, 2006: 5). Needless to say, when researchers from particular universities enter into a Europe-wide competition with excellence as its sole criterion, this will increase competition and differentiation. Moreover, such an ERC will 'set up benchmarks against which the best researchers in Europe can measure themselves' (Lambert & Butler, 2006: 57).

The new model also affected the second spatial level. The creation of a European space through collaboration now also aimed at excellence. In the field of research there was the intention of creating so-called networks of excellence (NoE) and integrated projects (IP) (CEC, 2003: 10, 18). In the domain of education there was the start of the

Erasmus Mundus programme at the Masters level. Unlike the classical Erasmus programme, the Erasmus Mundus programmes presuppose a selection of the programme as well as the participants on a competitive basis 'in order to attract to Europe some of the world's best students' (CEC, 2003: 11). Where for traditional Erasmus programmes almost all universities could participate, Erasmus Mundus programmes are selected on a competitive basis.

More so than in the classical Erasmus programme, the Erasmus Mundus programme defines the European space in terms of detachment or disconnection: the idea behind the programme is that students only enter a European space when they are confronted with different European cultures, which is why the programme requires them to pursue their studies 'in at least two European countries' (CEC, 2003: 11) during one academic year. While the US Fulbright scheme, which is Erasmus Mundus' main example, forbids a stay in more than one institution, under Erasmus Mundus such a stay in at least two member states is a key condition. Just as in collaborative research, a European space is seen as the negation of rootedness in a national space and culture. Entering a European space means detaching oneself from national cultures. It remains to be seen if such an uprooted 'European' experience where students from outside Europe are confronted with two or even three different cultures during one academic year (while classes are taught in English) will not leave them confused rather than enriched by a 'European' experience. All the same, in this sense Erasmus Mundus combines the two views of European space: from the organisers' perspective, it aims at collaboration, while from the participants' viewpoint it involves an experience of detachment or disconnection.

The third vision of a European space in terms of detachment is now also interpreted in terms of differentiation. Consider the Commission's recent idea to create a European Institute of Technology (EIT) (CEC, 2005: 12, 2006b: 2, 11; CEC, 2006a: 2,4) as a European counterpart to the MIT. Unlike the paradigm of coherence, the EIT wants to concentrate excellence. Yet rather than concentrating on excellence in a small number of existing universities – which could be the outcome of an ERC – the EIT wants to concentrate research in a separate European institute. Although the project has been toned down (CEC, 2006c), the Commission initially wanted excellent universities to 'second' their best researchers to a European institute where they would remain for several years (CEC, 2006a: 2, 8–9, 11–12).

A New Model, New Modes of Governance

Differentiation also changed the balance of power between existing players. Where the Bologna process aiming at coherence was mainly led by the Ministers of Education of member states, 'together with...non governmental European organisations', the model of differentiation is clearly guided by supranational agents, specifically the European Commission. More generally, the autonomy of universities vis-à-vis both national governments and the Commission is bound to increase under the new model. While cohesion still requires a nation state to implement common standards, the model of differentiation by contrast necessitates that the state give up its control over universities and increase their autonomy.

At the same time the new model also created new players, such as new advocacy organisations. While the Bologna Process is monitored and steered by the European University Association (EUA), the paradigm of differentiation is propagated by more 'selective' advocacy organisations. Where the EUA represents about 700 European universities, its more 'selective' counterparts like the League for European Research Universities (LERU) (founded in 2002) only represents 20 (from 'Oxbridge' to Leuven and Heidelberg), while the IDEA league which was founded in 2005 only represents five of the best 'technical' research institutions in Europe. Its four founding members are Imperial College London, Delft University of Technology, ETH Zürich and Aachen University – hence the acronym 'IDEA'. Both the LERU and IDEA 'leagues' explicitly represent the interests of top research universities and thus defend differentiation. A differentiated European area thus also causes a differentiation in advocacy groups.

Interestingly, the gap between the more inclusive and more elitist policy organisations is not as wide as one would expect: all seem to support differentiation which again suggests that there is indeed a paradigm at work. Even the more inclusive EUA states that 'universities accept that there is a tension between its necessary strengthening of research universities and the need to ensure resources for research-based teaching in all universities' (EUA, 2005: 4).

Although most actors involved agreed on the new paradigm of differentiation, the traditional differences on the European area between the Commission and these advocacy groups, old and new, continued. Once again two concepts of a European space conflict: a space in terms of common standards and infrastructures (this time serving differentiation and excellence) was again opposed to a European space as transcending existing national universities. As before, all participants agree on the first spatial vision: just as almost all endorse the Bologna process as a means to get more coherence, all now support the creation of a research council (ERC) as a way to increase differentiation. Yet when it comes to the more ambitious visions of a more integrated European space the Commission and the stakeholders again part company. Just as almost all advocacy organisations welcomed the ERC, so they almost unanimously rejected the 'European MIT' (the EIT) precisely because it was a separate institution, which was only defended by the Commission.

Critics of the Commission's more radical view of the European area may argue that true differentiation is incompatible with the Commission's more 'integrated' and controlled, 'top-down' views. While very few doubt that the ERC (like the National Science Foundation in the United States) is an efficient 'bottom-up' way to benefit differentiation, competition and 'excellence', many doubt the efficiency of a competition in which the Commission interferes. The Networks of Excellence indeed require lots of paperwork, are policy driven and not responsive enough to science (Lambert & Butler, 2006: 44), while the Erasmus Mundus programme in turn only accepts universities which already collaborate. All this means that truly excellent universities (like 'Oxbridge') are reluctant to apply to these programmes that then risk becoming excellent in name only.

Although old oppositions surface again, governance in the new paradigm of differentiation differs in crucial ways from that of coherence. Generally speaking, the stakes

under the paradigm of differentiation have become higher. Unlike the paradigm of differentiation, the model of harmonisation was simply less contentious and in that sense less political. This is hardly surprising, for who would object to increasing coherence of standards? This is why the Bologna process is often seen as an example of harmonious policymaking where all stakeholders are involved, thus showing that multilevel governance with 40 or so ministers and an equal amount of stakeholders around the table is indeed possible. Typical for coherence is also its inclusiveness: Erasmus and the Bologna process, for example, have as their goal to include as many institutions as possible and use hardly any internal competition for quality. In the field of collaborative research, too, there was *de facto* a marked absence of competition for excellent research teams. Instead a wide range of European research institutes participated, mostly evenly spread between north and south, west and east.

By contrast, the policy aiming at differentiation is generally more political not only because funding is differentiated on a competitive basis, but also because the available amount of funding is higher. The paradigm of coherence had no other incentive than the binding signatures of ministers or the award of relatively small-scale grants to students under the Erasmus programme. True, the Marie Curie grants and collaborative research involved a considerable budget. Yet the budget that is used to propagate the new model is considerably higher. The ERC will get its own budget of around €1 billion a year, while the Erasmus Mundus grants (to which, surprisingly, only non-EU citizens are entitled) are higher than those of the existing Erasmus programmes. The presence of funding as a mechanism of governance, then, means that the impact of the paradigm of differentiation is likely to be even higher than that of coherence.

Yet, as the debates get more political and the stakes get higher, consultation, and thus contestation, paradoxically diminishes. Indeed, the relatively broad and open consultation that had still characterised the model of coherence (think of the Bologna process), is now replaced by a top-down mode of governance. The creation of the ERC and the EIT was implemented fast and without much consultation. Despite a massive rejection of the idea of an EIT by various stakeholders and consultative bodies inside and outside the Commission (e.g. Sanders, 2006; Lambert & Butler, 2006: 5, 58–9; LERU, 2005), the Council and Commission initially went ahead with the idea (see CEC 2006a; CEC, 2006b: 2, 11). Only recently has the Commission moderated it, probably because some member states protested.³

How can we explain that, as the stakes get higher, consultation diminishes? A cynical explanation could be that when the budget increases, the space for democratic consultation decreases. Multilevel governance within the Bologna process is all well and good as long as there are no huge EU budgets involved. Yet I believe that this is only part of the story. The relative consensus on this top-down policy can also be explained by the language that is used to legitimise the creation of a differentiated European area. I believe differentiation is legitimised through a permanent ‘rhetoric of emergency’. The origin of and driving force behind this rhetoric lies in the Commission’s so-called Lisbon agenda which wants to make Europe the most competitive knowledge-based economy in the world by 2010.

True, this rhetoric of emergency was used by the Commission as early as 2000 when it declared that ‘the situation is urgent’ (CEC, 2000: 24). The motif increased even

further when the model of differentiation started guiding European policy. Ever since, the European area for research and education is depicted as being in a permanent state of emergency. In almost all Commission documents the dramatic weakness of European research and education vis-à-vis the United States and Japan is emphasised. This rhetoric became particularly strong when in 2004 for the first time an attempt was made to offer a global ranking of the 500 best universities in the world in what became known as the so-called Shanghai ranking (Shanghai Jiao Tong University, 2004). This ranking has been used ever since by the European Commission to legitimise its call for evermore drastic action (e.g. in CEC, 2005: 3 n.10; CEC, 2006a: 5n.6). Almost simultaneously another global ranking by the *Times Higher Education Supplement* (2004) came to similar conclusions. Why were these rankings so alarming? Tony Blair gave the answer to that question in the European Parliament in June 2005 when he declared that ‘of the top 20 universities in the world today, only two are now in Europe’ (Blair, 2005). Blair modestly omitted the fact that those two were in fact British, so that, with the words of the Commission, ‘apart from a handful in Britain, there are no European Union universities in the top 20 in the world and relatively few in the top 50’ (CEC, 2005: 3; CEC, 2006a: 5). Such a desperate condition, goes the line, requires and legitimises desperate measures.

Perhaps it is this rhetoric of a state of emergency which explains why the Commission is given such a strong mandate in this field and why it can operate in a swift and top-down way, as opposed to the more bottom-up procedures that were characteristic for the implementation of coherence. This is surprising given that initiatives propagating differentiation such as the ERC ‘have caused alarm in some EU countries, concerned that the drive for results will mean that EU money is pumped into elite institutions with the best research records mainly in Britain, the Nordic countries and the Netherlands’ (Laitner, 2005). Yet although many member states have reasons to believe that an ERC would go against their national interests, the Council has nonetheless supported the Commission in its creation of differentiated European space. However, it remains to be seen how things will evolve once the ERC starts working. Will member states in the south and the east accept a differentiated European landscape? Moreover, one can wonder if these countries are not ‘trapped in a vicious circle: they will get no more money unless they reform; and they cannot reform without more money’ (Lambert & Butler, 2006: 20, 38, 47, 55, 60, 65).

Epilogue: ‘Future Research’

Some may object that this chapter limits itself to examining the official discourse without actually researching how people experience changes in the European space at the grass roots level. One could for example ask if the Bologna process’s official intention to increase mobility, did not *de facto* decrease it, because of the rigid study structure it has created. While it is true that an analysis of texts by the Commission does not tell us if and how they are implemented and experienced at the grass roots, I believe that it is equally true that such analysis also precedes events at that level and can therefore identify tendencies that have not yet been implemented in practice. Despite all post-modern doubts about the idea of a ‘centre’, it remains true that most policies start at a

fairly limited policy level and is only afterwards implemented in reality. First there was the Bologna declaration and then the process, not the other way round.

For that reason, conceptual analysis may offer us an 'early warning system' to inform us that an educational earthquake may be underway. Only now, many years after its inception, millions of students and researchers in the European area are coming to terms with the consequences of the Bologna process. If we wait till the model of differentiation is visible in the field, then stakeholders and policymakers alike may (again) be caught off-guard by decisions they may not have foreseen or may not approve of. This, then, is the paradox: while we can only now see what the implications of a process such as 'Bologna' are in practice, it is precisely for that reason too late now to change dysfunctions. So, although conceptual analysis differs from an examination of what happens at grass roots level, it may still critically anticipate consequences at that level. How, then, can we try to anticipate consequences of the paradigm of differentiation?

First, we can obviously try to anticipate consequences by looking at the United States as an example of a differentiated area and hence one the Commission constantly invokes. One problem we can observe there concerns the social role of the (social) sciences on which the Commission had always taken an ambiguous position. On the one hand the Commission suggests that universities should be more open to society and should 'explain at home and abroad the specific value of what they produce for learners and society' (CEC, 2005: 4). Similarly, the Commission complains that 'communication between scientific specialists and non-specialists is much needed but often absent' (CEC, 2006b: 8). This openness to society ranges from developing policy oriented research to being 'open' to society and the market at large (e.g. CEC, 2005: 8) leading to a 'cross-fertilisation with the business-community and with the wider society' (CEC, 2006b: 4).

Yet on the other hand the Commission also states that 'universities should be funded more for what they do than for what they are, by focussing funding on relevant outputs rather than on inputs' (CEC, 2006b: 7). Yet the more output is measured in (and by) the social sciences, the more those researchers tend to publish in highly specialised journals. This in turn means that they will be less likely to publish for a wider audience (as this is not acknowledged as relevant 'output' in most rankings) and that they will be less likely to develop more general positions addressing a wider audience (as these seldom conform to what is required in specialised journals) or simply have less time to communicate to a larger audience (Lipsett, 2006). In short, this risks undermining the 'public mission and overall social and cultural remit of universities' (CEC, 2006b: 6).

Here the European Commission risks reproducing the paradox that characterises its admired American example: while the United States has the best research universities in terms of output, its universities host arguably less 'public intellectuals' in the social sciences than Europe. The question will thus be if the paradigm of differentiation will not lead to a 'neutralisation' of the social and political role of academics in the (social) sciences, and if, in so doing, Europe risks not losing one of its typical cultural values in the name of an American model that may be particularly deficient in this respect.

Another problem we can observe in a differentiated area such as the United States is that the university and the knowledge it produces are seen 'in terms of a generalized logic of "accountability" in which the University must pursue "excellence" in all

aspects of its functioning' (Readings, 1996: 3). In the same way, the Commission also supports 'external quality assurance' (CEC, 2005: 7), and relates it to 'clearly defined targets and indicators' (CEC, 2006b: 8) or to the presence of professional management in universities, allowing 'professionals from outside the purely academic tradition' within 'universities' management and governance structures' (CEC, 2003: 17 and 9, 2005: 9, 2006b: 5). However excellence and accountability then often tend to be reduced to 'exhaustive accounting', 'bookkeeping' and evaluation (Readings, 1996: 18, 26, 29, 32, 130–34). As a result, the university increasingly needs administrators, which explains why (American) universities understand themselves 'solely in terms of the structure of corporate administration' (Readings, 1996: 29). Yet one can wonder if this reflects the universities' mission. Is the knowledge the university produces and teaches something that can be measured and quantified? Can its accountability be reduced to accounting? Shouldn't its mission resist any 'final determination' rather than embracing a narrow definition of excellence 'as an *alibi* that might excuse us from the necessity of thinking about what we are saying, when and from where we are saying it'? (Readings, 1996: 160).

But we can, secondly, also learn positive lessons from the United States like the importance of access. It is not easy to reconcile a differentiated area with the Bologna process' 'commitment to making quality higher education equally accessible to all' (The European Ministers of Education, 2005: 4) as differentiation normally implies a diversification of students on the basis of intelligence. Yet such a differentiated landscape also means that universities need more money, which almost inevitably implies that tuition fees will be introduced (Lambert & Butler, 2006: 4). This in turn signifies that there is a risk that some of the best students from a less privileged background will no longer be able to study. A differentiation will then reflect differences in wealth rather than in talent.

If a diversified European space really wants to attract the best rather than the richest, thus 'breaking the link between social origin and educational attainment' (CEC, 2005: 6) then it needs an extensive system of grants, like in the United States or the United Kingdom. The Commission indeed emphasised that 'it is crucially important to maintain the excellence of teaching and research... while still ensuring broad, fair and democratic access' (CEC, 2003: 6, 13–15, 2005: 10). Against many in (continental) Europe who believe in the 'automatic right of access to university studies' (CEC, 2003: 14), the Commission argues that 'tuition fees could in practice provide better access for students from lower income groups if the incremental funds were recycled into a sound aid system' (CEC, 2005: 8). Put more bluntly: the 'use of the access argument to justify free higher education for all university students is simply a piece of middle class special pleading' (Lambert & Butler, 2006: 52). The Commission concretely suggests that 'where tuition fees are introduced, a substantial part of the funds should be redistributed as income-contingent grant/loans aimed at guaranteeing access for all, and as performance-related scholarships aimed at encouraging excellence' (CEC, 2005: 10). However, most governments or advocacy groups which are (slowly) implementing the paradigm of differentiation did not follow the Commission's advice for compensating talent-based grants (partly financed by tuition fees) for the less well off. This is worrying, as the European diversified space risks become more unequal than its

American counterpart, where excellence is at least in part combined with an extended grants scheme.

Another thing we could learn from the United States, as the Commission admits, is fostering certain values and practices in higher education, such as valuing interdisciplinarity, fundamental research, autonomy and career prospects for (young) researchers and so on (Lambert & Butler, 2006: 44; Ingdahl, 2006; CEC, 2003: 8–9, 2005: 9). Yet although a successful implementation of differentiation requires such values and practices, implementing this will be very difficult.

A third and final way to predict problems is by focussing on the United Kingdom as a European country where differentiation is already implemented, the results of which can now be observed. One striking result is that teaching becomes less important than research, as ‘competitive funding . . . based on institutional evaluation systems and on diversified performance indicators’ (CEC, 2006b: 8) means – *de facto* – attributing funding on the basis of research output. This too is worrying. While the United States has the best research universities in the world, when it comes to quality of undergraduate teaching at those research universities, some top European research universities particularly in the United Kingdom, are arguably better in some respects. Think of ‘Oxbridge’ and its particular tutorial system, which involves top researchers (and not graduate students, as is the case in the United States) offering small-scale tutorials for undergraduates. Yet, precisely as a result of ‘more competition-based funding in research and more output-related funding in education’ (CEC, 2005: 8), this undergraduate teaching system and the colleges that provide its particular context are currently under threat. For if careers of academics depend increasingly on research output rather than commitment to undergraduate teaching and university life in general, then such commitment risks being undermined.

A further problem is related to the way a differentiated area is created in the United Kingdom. While the United States already has an established differentiated university landscape, European countries like the United Kingdom try to get one of its own through ‘the highly artificial creation of a fictional market’ (Readings, 1996: 36) by using government funding. This concretely means that the British government creates ‘a unified . . . accounting mechanism’, such as the Research Assessment Exercise (RAE), in order ‘to accentuate differentials in perceived quality rather than to reduce them. Thus more money is given to the high-scoring university departments, while the poor ones, rather than being developed, are starved of cash’ (Readings, 1996: 36–37).

However, given that ‘the taxpayer’s money’ is involved, the procedures that are used to award competitive funding tends to involve a hugely bureaucratic system of auditing, surveillance and controlling researchers (Readings, 1996: 36–37). Ironically, when it comes to higher education policy, the United Kingdom has now become a precursor of a bureaucratic system that is normally associated with ‘Brussels’. As a result, the United Kingdom, and tomorrow’s Europe, risk creating an artificial university ‘market’ or ‘area’ that involves much more bureaucracy and government than the American area they wanted to emulate. Yet this may have unintended outcomes. Indeed, such bureaucratic control may even become counterproductive, not just because it takes away time from researchers, but also, and more importantly, because it starts from the assumption that researchers cannot be trusted, which may damage their ‘professional pride

and integrity' and build 'a culture of suspicion, low morale, and may ultimately lead to professional cynicism' (O'Neill, 2002: 50 and 57). With the exception of Readings' (1996) work, it is perhaps no coincidence that these trends are mainly examined by British academics such as Onora O'Neill (2002), David Marquand (2004), Michael Power (1997) or Marilyn Strathern (2000).

These are just some telling examples of a bureaucratic tendency to measure and 'objectify' knowledge, research and teaching which is not limited to the United Kingdom alone: what happens in the United Kingdom and some other European countries today may happen in the rest of Europe tomorrow. As we have seen, the creation of a European area for higher education and research also changes the reality of a European university. Yet despite this, these European universities themselves are hardly reflecting on these and future changes. Compared to the scale of the changes that are currently affecting the European area, academic research about these changes is relatively rare, and within this under-researched field only few researchers offer a critical perspective. Given this gap between the dramatic changes in the European university landscape and the universities' own lack of (critical) research on these changes that will nevertheless determine their future, an appeal for more research is justified.

Notes

1. 'CEC' stands for 'Commission of the European Communities'
2. I distinguish differentiation (of tasks and profiles) from diversity (of culture): while harmonisation can be compatible with cultural diversity, it does not necessarily imply functional differentiation (or stratification). Moreover, like the Commission, I use the term differentiation, although I am aware that others argue that it is better to use the term 'diversification' (Huisman, 1995).
3. Even the influence these member states retained over the Bologna process or over the collaborative research is now replaced by institutions such as the ERC or the EIT that are autonomous from either the Commission or the member states.

MAMMON, MARKETS, AND MANAGERIALISM – ASIA-PACIFIC PERSPECTIVES ON CONTEMPORARY EDUCATIONAL REFORMS

Anthony Welch

If the world in general has changed profoundly over recent decades, so too has the world of education, in ways that reshape all who interact with it, whether educators, students, or parents. Educational institutions too, have been re-fashioned substantially, and all too often, it seems, by forces well outside education, and according to principles that have little to do with education.

Within the North, the ebullience of the post-war decades has largely gone, and the post-war Keynesian settlement replaced by a much more austere and technicist world of markets and managerialism (Clarke *et al.*, 2000; Considine & Painter, 1997; Gee *et al.*, 1996; Yeatman, 1997). Within the South, including some socialist states transitioning to a market economy, markets and managerialism have been seen as key strategies with which to promote development, reform the rigidities of the state socialist model, and leapfrog directly into a modern knowledge economy. Within education, the determination that post-war capitalist, or post-revolutionary socialist generations, would not be disfigured by structures and ideologies that created and sustained class, ethnic, and gender inequalities, has now been largely overtaken by a fissiparous reform programme, that often sets groups, institutions, teachers, parents, and students against one another. (This is not to say that the former more egalitarian ideologies were always successful in achieving their goals; rather that the goals were different, and equality accorded a higher priority.)

This chapter sketches some of the main tenets of this renascent ideology, making the point that it is not the first time that such ideologies have reformed (and arguably deformed) education. Some of the mainsprings of markets and managerialism are first outlined. A sketch of earlier episodes of the introduction of business efficiency schemes into education, both in Britain and the colonies, and the effects on pedagogy, curriculum, and financing of education, as well as upon teachers, and pupils, is followed by some select examples of contemporary reform programmes, within schooling and higher education systems, from various contexts. The sketch of major reform moments in education within the Asia-Pacific region, specifically in both Australia and China, serves to illustrate the capacity of contemporary ideologies of markets and managerialism to transcend political and cultural differences, and levels of development.

Mainsprings

After briefly tracing core assumptions underlying markets, and managerialism, some of the likely ways in which each finds expression in education are outlined. Theories of educational markets are understood in more theoretical terms, and seen to rest on theories of choice, while managerialism is seen to offer a technology of implementation, including benchmarks with which to measure progress towards the attainment of market goals. While in each case, contra to the claims of hyper-globalists such as Ohmae (1991, 1995), state strategies do make a difference, (Weiss, 1998; Welch & Mok, 2003), it is equally true that the agendas of major global agencies such as the World Bank, Asian Development Bank, and the OECD have been significant in pressing, for example, ‘a less interventionist...state,...and a preference for market-like mechanisms over bureaucratic methods of service delivery’ (World Bank, 1995: 12).

Markets

Markets in education are justified by an appeal to the notion of choice, and the argument that state-dominated systems denied much, if any, choice to families, parents, and students. By contrast, it is argued, individuals should be free to select an education that they believe best caters to their interests and aspirations, and should also be responsible for the outcomes of that choice. According to this argument, individuals and families compete for advantage in education. Within market discourses, education is seen as a positional good, in which those who have the knowledge and opportunity, use education for purposes of achieving greater status, and a better position in the socio-economic hierarchy (Gewirtz *et al.*, 1995). Choices are often made more on the status of an educational institution, whether school, college, or university, rather than the quality of education it offers. Individuals gain advantage through gaining access to prestige education, but (it is sometimes admitted) this is at a cost to others: ‘Positional competition...is a zero-sum game. What winners win, losers lose’ (Hirsch, 1976: 52). Despite substantial evidence that class effects mean that the more sophisticated choosers can compound their social and educational advantages (Gewirtz *et al.*, 1995; Gilborn & Youdell, 2000; Campbell & Sherington, 2006), while those whose cultural capital equips them less well in the competition stakes fare much less well, market ideologies continue to thrive. As a result, a more fissiparous society eventuates, where the gap between the ‘haves’ and ‘have-nots’ widens as a direct result of the extension of educational markets.

This is not the whole story, of course: it is not just individuals who comprise the market. Institutions, too, increasingly compete. It is now often said that rather than students choosing schools, schools are often choosing students, in carefully orchestrated marketing campaigns (Ball, 2007; Campbell & Sherington, 2006). While more advantaged schools (in terms of location, social class composition, or with low proportions of children whose first language is not that of the majority) are able to trade on these attributes to forge further ahead, schools in poorer areas, rural environments, or with high proportions of migrant children who must learn the majority language as their second language) often fall further behind, becoming less and less attractive

both to parents and funding agencies. According to market ideologies, parents and children frequenting such schools may then effectively be blamed for their own failure to choose a better school.

In both Australia and China, the fostering of market ideologies in education, as in other social policy arenas, has been a concomitant of a changed view of the shape and role of the state. The two contexts were very different of course – while in China, the ending of the private sector in education after 1949 followed from the principle that the state was responsible for all provision of education, in Australia, there had long been a significant private sector, most particularly at the secondary level (Campbell, 2007). The rise of a more economistic ideology in the latter in the 1980s saw the increasing subordination of education to the language and logic of economics, and the subsequent progressive extension of marketization to the public sector. In China, the period of its opening, after the turbulence and retreat from the outside world of the Cultural Revolution, also coincided with the decade of the 1980s, and heralded the end of the iron rice bowl, whereby the state had guaranteed employment for life, and large and often unwieldy state-owned enterprises (SOEs) delivered a full range of services, including schooling, to their workforce.

Managerialism

Managerialism in education is arguably an outgrowth of wider neo-liberal reform programmes of the past decade or two – often termed ‘economically rational’ in Australia (Pusey, 1991). Such programmes have not merely led to greater privatization and decentralization (although as some have pointed out, the directed character of the latter means the process might be better characterized as centralized decentralization), but have also – in an apparent paradox – led to increased regulation of educational institutions. It is the latter process that interests us here. In an era in which funding per student for public sector educational institutions has plateaued or declined in many systems, in effect this means that education has come under increasing pressure, but also paradoxically, under increasing scrutiny or surveillance (Cowen, 1996; Miller, 1995a and b; Sheehan, 1996). As much as a decade or more ago, the effects of this ideology were being pointed out in countries such as Australia:

[W]hile hard-pressed staff in schools and universities must do more and more with less and less, they are less free to engage in democratic action and resistance. They are increasingly beset by detailed external and internal demands which affect both how they spend their time, and which increasingly impose directly upon curricula, evaluation and pedagogy – all in the name of accountability or devolution. (Welch, 1997: 17)

The basis for managerialism rests on an appeal to technicist principles of efficiency and economism (Habermas, 1971, 1974, 1976, 1978; Pusey, 1991; Welch, 1997, 1998, 2007a) that represent the historical triumph of a means-end, that is instrumentalist rationality over older forms of reason that enshrined ethical concerns about the social good (such as that of the ancient Greeks, for example, whose maxim ‘Man is the

measure of all things' was effectively countered by the new logic of efficiency and economism). An alternative account was offered by Lyotard, whose notion of performativity critiqued the historical process whereby knowledge has become commodified and transformed into one of the principal productive forces in society. Under such conditions he argued, notions of productivity like 'optimising the system's performance' (Lyotard, 1984: xxiv) become the ultimate goal, and the relevant system technology is drawn from the discourse of business and management. Enhancing worker productivity, including by the use of new technologies such as ICTs, forms the new techno-logic of performativity. Performance targets are set, and individual workers compete against each other for rewards and punishments. This new regimen means that questions drawn from the discourse of business efficiency come to dominate: 'Is it efficient?' or 'Is it saleable?' become more important and more common questions than 'Is it true?' (Lyotard, 1984: 51).

Historical Antecedents

As argued above, a key technology of managerialism is the idea of rewarding workers according to quantitative performance targets. While this provides a starting point for understanding why they were introduced, and what influence they have on educational policy, it remains to chart their effects in practice. In the Anglo-American democracies described above (countries such as New Zealand, Canada, the UK, and Australia), performance indicators have flourished in recent decades, to the point where they have become an integral weapon in the managerialist armoury – within education, just as in health, welfare, and other public policy arenas. But not for the first time: before managerialism, there was efficiency. A brief review of one or two examples of efficiency movements in education, from the nineteenth and early twentieth century, serves not merely to show the principal effects of this ideology, but also provides an excellent reminder of the lessons of history, at least for those who still wish to learn.

Payment by Results

The first example, drawn from the mid nineteenth century, was, like much educational baggage of the time, imported by numerous colonies from England. Among other things, it also serves as a timely warning to current hyper-globalists, such as Ohmae or Greider (1997) who insist that the impact of globalization effects on current policy agendas is an entirely novel phenomenon. Importing policies from the UK, or elsewhere, is by no means new.

The Revised Code, or *payment by results* as it came to be widely known, was introduced into British education around the 1860s, its rationale encapsulated in the proud boast of its proponent to the British parliament: 'If it is not cheap it shall be efficient; if it is not efficient it shall be cheap' (Maclure, 1974: 79–82). Its legitimacy stemmed from the strong prevailing current of business accountability, and efficiency, that informed education inquiries of the time, in particular arising from the report of the Newcastle Commission: 'The Commissioners held the common view of the period, that the notion of accountability, so vital to a well-run business, should be applied

vigorously to all forms of government expenditure' (Musgrave, 1968: 35). Within years, it had been introduced into several of the Australian colonies (Turney, 1969: 229–32; Miller, 1986; Rodwell, 1992), and to India (D'Souza, 1976; Allender, 2006).

The original British scheme was largely inspired by middle-class fears of rising calls upon state funds for elementary schools (provided for the working class), at a time of swelling demand for education by and for that group. In an effort to rein in justified rises in expenditure, the needs of a 'business age' specified that a 'standard' be established which each child had to attain to pass at that level (Musgrave, 1968: 36). This standard was based upon the assumed needs of industry for a literate workforce and bourgeois assumptions about a curriculum appropriate to the working class: the three Rs, suffused by Christianity.

The effects of the scheme were swift and dramatic – in the face of rising demand, the state grant for primary education promptly fell by more than a quarter, and a sharp decline ensued in numbers of pupil teachers and teachers' college trainees. The teacher/pupil ratio worsened profoundly: from 1:36 in 1861 to 1:54 five years later (Maclure, 1973: 81).

Other perverse effects included inducing teachers, whose annual salaries were now tied to the numbers of pupils in their classes and to their performance at particular exams, to cheat. Teachers drilled their pupils mercilessly on test items (Hyndman, 1978: 34) once the inspector's visit was imminent. Some secretly trained their pupils in classroom tricks that would create a more favourable impression. Yet others falsified enrolment registers, to keep numbers artificially high. Sick children were dragged along to school to satisfy attendance requirements, upon which teachers' salaries were dependent (Hyndman, 1978: 37), while teachers now had to negotiate their salaries directly with school managers (Welch, 2007a).

Cramming, rather than teaching, became the means to ensure a teacher's livelihood – weakening pupils, teachers, and pedagogy. Hence, a further product of the Revised Code was a narrowing of the curriculum and a narrow instrumentalism with respect to educational aims. Overall, while the scheme was justified by appeals to the principle of 'efficiency', it was in fact introduced largely as a means of curbing justifiable growth in state expenditure on education.

As with the Indian experience (D'Souza, 1976; Allender, 2006), and at much the same time, the Australian schemes inherited all the weaknesses of the British. The introduction of the so-called Standards of Proficiency into New South Wales for example, insisted that teachers follow set requirements scrupulously, and a similarly detailed examination of requirements by inspectors. The effects on each was to mechanize the labour process. Teachers, whose promotional prospects were directly tied to their pupils' results in the test, were led to implement 'rote learning and... mechanical modes of instruction' (Turney, 1969: 230), while '[t]he work of the inspector largely became one of mechanical examining and his reports became mainly based on statistical analysis of results' (Turney, 1969: 231). In the colony of Victoria, for example, *payment by results* was acknowledged to have achieved 'the encouragement (of)... memorization rather than reasoning (of) formal, mechanical teaching methods, and... keeping the curriculum narrow' (Barcan, 1980: 107; see also Rodwell, 1992).

Taylorism or Scientific Management

The 'payment by results' scheme in England, India, and various Australian colonies in the 1860s were not the only ones to use business efficiency to promote ideological reforms in education. Taylorism, or scientific management, cut a swathe through American schools and universities in the period around the First World War. Originally introduced into manufacturing industry in an attempt to boost productivity (the amount produced per worker), the success of *scientific management* in extracting more output per input attracted those concerned to hold back or reduce spending on education. Business interests were particularly concerned, under the banner of efficiency, to reduce state educational costs (termed 'wastage'), while also shifting the financial burden of apprenticeships away from industry, which had been their traditional training ground.

The imposition of this *cult of efficiency* as it was dubbed (Callahan, 1962; Welch, 1998), impoverished education. But not just costs were reduced: the curriculum was narrowed to become more like vocational training, while the education system's capacity to respond to diversity – African Americans (then called Negroes or blacks), rural dwellers, poor whites, and the growing ranks of American immigrants – was equally attenuated.

The rationale for implementing *scientific management* in schools and universities was based squarely on an argument that:

consisted of making unfavourable comparisons between the schools and business enterprise, of applying business–industrial criteria (e.g. economy and efficiency) to education, and of suggesting that business and industrial practices be adopted by educators. (Callahan, 1962: 6)

Within years, not merely had the *Atlantic Monthly* championed its introduction into education, but even The National Education Association. By 1907, popular books on education argued that classroom management could be seen as a 'business problem'. By 1910, it could be claimed that:

Our universities are beginning to be run as business colleges. They advertise, they compete with one another, they pretend to give good value to their customers. They desire to increase their trade, they offer social advantages and business openings to their patrons. (Callahan, 1962: 7)

School boards were made smaller, sometimes considerably, and became dominated by businessmen interested in reforming school administration along financial lines. This represented a profound retreat from earlier reforms of some of the best-known school administrators such as William T. Harris, Horace Mann, and Henry Barnard, whose reforms were motivated by broader and deeper interests in education, and a stronger background in the field, rather than the field of business.

A final change provoked by the rising tide of business ideology in American education at this time was curriculum reform, where the principal push was to make

the curriculum ‘more practical’. Major business moguls, such as Andrew Carnegie, Cornelius Vanderbilt, and John D. Rockefeller, argued that their success had nothing to do with ‘book learning’ but was based on good old-fashioned common sense married to the kind of business acumen that could not be taught in schools. Carnegie was particularly scornful of college study: ‘In my own experience I can say that I have known few young men intended for business who were not injured by a collegiate education’ (Callahan, 1962: 9).

According to this ideology, Business English should be substituted for composition, and business principles, contracts and bookkeeping be introduced into schools. At least for those not proceeding to high school, and arguably for all pupils, the ‘love of learning’ should be subordinated to the ‘love of earning’ (Callahan, 1962: 10), a view that also licensed the proliferation of vocational courses in schools.

The preceding historical examples of the implementation of ‘efficiency’ policies in education serve as useful pointers to more modern ideologies of markets and managerialism in education. Among principal effects of earlier episodes were the following:

- A narrowing of the curriculum, and heightened emphasis upon vocationalism (see also Kliebard, 1999)
- Lower quality teaching, caused by cramming and ‘teaching to the test’
- Significant cost reductions in real terms, leading to much higher class sizes, and fewer teaching recruits and
- Less effective capacity to respond to cultural diversity and working class pupils.

Markets and Managerialism in Australian Education

Notwithstanding the above, we should not be too surprised that the results of earlier episodes, when education came to be dominated by ideologies of business efficiency, have little influenced populist politicians, selected educational critics, and media hacks, who peddle similar principles in modern guise. The following select examples from Australia, and China, underline not merely the easy popularity of such schemes, but also the failure of the policy process to attend to the lessons of earlier episodes.

Notwithstanding the corrosive critiques of the incorporation of business efficiency models into the world of social policy by figures such as Habermas and Lyotard, managerialism has been widely implemented in the Australian state (Painter, 1997), and its reform agenda widely touted, including within education (Miller, 1995a, b). Entire management technologies such as Total Quality Management, borrowed from the commercial world, have been used to regulate educational institutions. A recent variant to be incorporated into some schools and universities is the ‘Balanced Scorecard’ management technology, replete with Key Performance Indicators, and coloured flags that indicate progress towards goals. Red indicates danger, of course.

The rise of markets in education has had a profound effect on Australian universities, technical and further education (TAFE), and schools in recent years, as institutions (both private *and* public) increasingly compete for students, or at least for a greater share of certain kinds of students. Hence the birth or expansion of performing arts high schools, academically selective high schools, sports high schools, technology

high schools, schools that offer an international curriculum such as the International Baccalaureate, and institutions that market a curriculum based on a particular religion (various Christian or Muslim schools, for example). Universities are also enmeshed in this market, competing vigorously for both local and international enrolments (Welch, 2003).

Justified by an appeal to choice, the Australian strategy was twofold. The first was, since choice entailed more than choice within the public sector, to expand the private sector in education. While most of the energy here has been expended on shifting resources from public schools to the private sector (Welch, 2003, 2007a; *Sydney Morning Herald*, 2000a, b, c), the beginnings of such moves in higher education (which has in Australia traditionally been entirely public), may now be discerned.

In the process, whereas marketing was formerly restricted to the private sector, the principle and practice has now become firmly ensconced within the public sector, with vigorous competition for the best students. In some states (like Canada, the USA, Germany, and Australia), the process of competition within the public sector has been deliberately intensified by the creation of selective high schools, at least in some states, which now often attract many more applicants than they could conceivably accommodate. The effects on the mainstream neighbourhood high school of this retreat from the former idea of a common school have been predictable, with research revealing their progressive residualization (Campbell & Sherington, 2006; Campbell, 2007). Within the Australian university system, the former fiction that all universities were much the same has now been exploded by the formation of various splinter groups within the sector. Examples include the Group of Eight (Go8), which (like the Russell Group in the UK) collectively dominate the race for research income; the New Generation Universities, Innovative Research Universities, and other such groupings.

The second strategy was to induce a climate of market competition within the public sector, whose schools were to be encouraged to compete vigorously, not merely with other state schools, but also with private sector institutions. Hence, the successful academically selective state high schools in New South Wales, most of which are creations of the past 20 years, now tout their academic results, which now often outshine those of wealthy private sector academies, whose parents pay fees of as much as A\$20,000 per annum, while mainstream state high schools are now encouraged to compete against low-fee denominational high schools, which have proliferated over the last decade, as seen below.

A further example of marketization in Australian education is evident in specific attempts by state and federal governments to foster the private schooling sector. In an effort to promote 'choice', state and federal governments have made more public funds available for the purpose of extending the private sector, something that has resulted in a plethora of new, largely low-fee Christian, schools being founded over the past decade, since the Howard Federal Liberal government came to power. (In Australia, the Liberal Party is of conservative persuasion, and can be compared with the Conservatives in the UK or the Republicans in the USA).

The changes indicated in Table 1 were underpinned by specific funding mechanisms, such as the now-notorious Enrolment Benchmark Adjustment (EBA) formula, introduced by the Howard federal government, soon after coming to power in 1996.

Table 1. Number of schools by sector, and percent change, Australia 1984–2004 (From Campbell, 2007: 223)

Year	Government		Catholic		Independent	
	<i>N</i>	% change	<i>N</i>	% change	<i>N</i>	% change
1984	7,544	–	1,705	–	776	–
1994	7,159	–5.3	1,699	–0.4	821	+5.5
2004	6,938	–3.2	1,695	–0.2	982	+16.4

Note: In Australia, the Independent sector embraces a small number of Catholic, non-systemic schools as well as those run by other religious sects (mostly Christian, but also Jewish, Muslim, etc.), and some progressive schools (such as Steiner or Montessori). In fact, the term Independent is something of a misnomer, and might be better termed ‘state subsidized’. Fees range from moderate to highly exclusive.

The formula transferred significant federal government funds to any private school, from a public school, for each pupil that transferred his or her enrolment from the latter to the former. The parallel deregulation of the establishment of new private schools (that previously had to establish a case based on need, and insufficient educational resources existing in the area) allowed 76 new schools to be established within four years, in the most populous state alone (Welch, 2007a: 27). In the face of widespread criticism, the EBA was abandoned, in favour of the so-called Socio-Economic Status (SES) formula, introduced in 2000, that has also been widely criticized for failing to take into account the actual wealth of parents who subscribe to such schools, but just depending on the blind law of SES averages for that community (Welch, 2003). In this way, for example, wealthy rural parents, may well have the enrolments of their children at high-fee, socially exclusive private secondary schools, effectively subsidized.

The actual logic behind this creation of an educational market by the federal government is illustrated in a revealing comment by the federal minister of education of the time:

We have to realize... that parents who send their children to non-government schools are saving taxpayers a vast amount of money – about two billion dollars a year, more than that... and that money is then available for the funding of government schools. (Welch, 2003: 276)

The parallel introduction of the federal schemes sketched above to divert funds from public schools to private ones, without increasing the size of the budget in real terms, ensured that the monies ‘saved’ by the taxpayers, did not extend support of public schools.

An example of the insistent use of managerialist performance indicators was seen in the actions of an Australian Federal Minister of Education, who, in 2005, used the threat of withholding funding to state governments as a means to introduce compulsory reports on performance by schools across the country. At the same time, the same federal minister pushed strongly for teacher attendance and productivity records, and the return to an ‘A, B, C, D, E’ grading system. Three billion dollars was at risk in

the most populous state (New South Wales) alone, until the state government finally relented, demanding that their schools ‘tell it like it is’ (*Sydney Morning Herald*, 2005a, b). While parents may well appreciate more information from schools about their children’s performance, the introduction of the machinery of testing, and grading, can end up distorting, rather than strengthening, the core education and mission of better quality teaching and learning, as was seen in the historical examples illustrated above. The arbitrary use of such indicators as the number of pupils at a school that achieve in the top 10% of literacy or numeracy tests, represents another example (Welch, 2007a: 14). Assumed in this ideology of managerialism is that success in meeting such performance targets, equates to improved quality of education, something that the historical examples treated above show to be at best dubious. Nonetheless, by such measures is the performance of educational managers (school principals, heads of department, Faculty Deans) often now measured.

Markets and Managerialism in Chinese Education

While profound differences exist between Chinese culture, society, and polity, and that of Australia, China has not proved immune to the effects of marketization and managerialism, including in education. While the effects can be seen at school level, the contemporary world of Chinese higher education presents clear illustration of its effects.

In China, too, the last decade or two has seen the development of educational markets. Once again, governments have driven this reform, as part of a wider agenda to reform education, and use it to bolster economic growth and scientific development. While Chinese families have, since Confucian times, valued education highly, and sacrificed a good deal to provide the best possible educational opportunities for their children, now families are increasingly becoming enmeshed in an often intense competition to get their child into a more selective school, that will in turn assist transition into a more reputable university, among the 1,600 or more degree-granting institutions across China. The result is a widening of the gap between ‘haves’ (those in the wealthier East of China, especially in major cities such as Beijing, Shanghai, Tianjin, Hangzhou, and Guangzhou), and the ‘have-nots’ (those in China’s West, minorities, rural peasantry) (Welch & Yang, 2007) This has been deliberately fostered by government policies, notably the 211 Project that selected certain universities for substantial additional funding, and the 985 Project, which was even more selective, and was scheduled to invest a total of some US\$4 billion, particularly in the nation’s leading universities, such as Peking University, Tsinghua, Fudan, and others.

Stimulated both by the effects of the regional economic crisis of the late 1990s, internal advice by key economists, and external advice by the World Bank (1999), which argued that ongoing restrictions to higher education access would pose a threat to the continuation of China’s high economic growth rates (almost 10% per annum during the 1990s), the emergence of a new market in Chinese higher education is seen in specific reforms of the past two decades (Mok, 1999, 2001, 2007). These notably included the creation of university-related companies (somewhat similar to the corporate

entities established by universities in the West, that are designed to commercialize specific products or technologies, based on research discoveries at that institution). Other examples include the development of a vigorous private sector of *minban* (the preferred term, within a socialist market economy is ‘people’s colleges’), that are rarely associated with a major public university, and that charge substantial fees, with lower entry criteria. This growth of the private sector was enabled by the passage of key pieces of legislation, titled ‘The Law on the Promulgation of Non-Governmental Education’, and regulations that governed forms of cooperation between Chinese and foreign interests in education (OECD, 2003; Huang, 2003a, 2003b). The latter arm of the market strategies in higher education insisted, for example, on reputable partners, detailed documentation, a Board comprised at least 50% by Chinese citizens, and a Chinese director (Huang, 2003a, b).

Erji xueyuan (second-tier colleges, always associated with a ‘mother’ university), *duli xueyuan* (independent colleges), and *fenxiao* (branch campuses) are other initiatives that are further segmenting the market. Supported by government, they are effectively profit-making arms of public universities (Yang, 2007), sometimes in association with local business personalities, who for the use of the public university’s name return part of the profits to the university. In some cases, the deals are part of a much larger exercise in land speculation, with the business person acquiring substantial land for development purposes.

Managerialism became part of a wider agenda aimed at promoting rapid expansion of higher education, which as early as the Fifteenth Party Congress (1997), was seen as critical to the development of China’s science and technology capacity. Influenced also by World Bank research that showed that restrictions to higher education acted as a brake on economic development, the Chinese government acted to rapidly expand higher education enrolments, but without commensurate increases in levels of staff or other resources. Table 2 shows the dramatic rise of enrolments, in absolute and percentage terms.

The effects of this massive tide of enrolments were predictable, of course – a substantial rise in the productivity of universities, as measured in strictly economic terms. Clearly, many more students were entering and proceeding to graduation, but with much-reduced levels of staff and other resources than had been available previously.

Table 2. Number of Public HEIs and Enrolments, China, 1990–2002 (Partly adapted from Yang and Ngok, 1990 to 1999 figures *China Statistical Yearbook 2000*; 2000 to 2002 figures from <http://www.moe.edu.cn/stat/tjgongbao/4.htm>)

Year	Number of institutions	New students	Graduates	Student enrolments	Percent increase
1990	1,075	609,000	614,000	1,206,300	–
1995	1,054	926,000	805,000	2,906,000	140.9
1998	1,022	1,084,000	930,000	3,409,000	17.3
1999	1,071	1,597,000	848,000	4,134,000	21.2
2000	1,041	2,206,072	949,767	5,560,900	34.5
2001	1,225	2,682,800	1,036,300	7,190,700	29.3
2002	1,396	3,205,800	1,337,300	9,033,600	25.6

One index of decline consisted of staff/student ratios, which worsened dramatically in the late 1990s and early part of the new century. From 1:5.22 in 1990, the ratio had reached 1:13.5 by 2001. (It should be pointed out that it is customary in China to include the rather numerous university administrative staff in such calculations.) Ongoing laments about declining quality and increased work-related stress by Chinese colleagues are paralleled by reported difficulties of accommodating students in dormitories and the lack of other resources with which to teach this huge swell of students effectively.

Conclusion: A New Cult of Efficiency in Education?

What is evident from the previous analysis? Perhaps the first point is that little has changed. A depressing failure to pay heed to the evidence of earlier instances that show that attempts to foist educational markets and business concepts of administrative efficiency upon educational institutions, in the mid nineteenth and early twentieth centuries, led to a decline in both quality and morale within the institutions, as well as a reduced capacity to deal with difference effectively, has meant that much the same mistakes are being repeated at the end of the twentieth century, and the beginning of the next.

Secondly, despite profound differences between China and Australia, markets and managerialism have triumphed in each at the end of the twentieth century, underlining the capacity of this ideology to transcend political and cultural differences. Indeed, the rise of these ideologies parallels wider trends in the Asia-Pacific region (Welch, 2005; Welch, 2007b), notwithstanding significant differences in the responses to this agenda, by individual states (Weiss, 1998; Welch & Mok, 2003). While the diversity of response forms a useful cautionary tale for the hyper-globalists, the widespread rise of current ideologies of markets and managerialism is both impressive, and worrying. The coalescence of mammon, markets, and managerialism has been shown, above, to have reduced the quality and effectiveness of education, as well as the morale of educationists, in institutions that are increasingly subjected to associated technologies of regulation. The underlying goal of increasing productivity, as measured in economic terms, leaves education poorer in every sense.

LIFELONG LEARNING AND GLOBALISATION: TOWARDS A STRUCTURAL COMPARATIVE MODEL¹

Peter Jarvis

Any comparative study of lifelong learning in a globalised world runs into a number of major problems since lifelong learning is not a structural system like other sectors of education but once we raise this question it follows naturally that we can ask to what extent is it possible to study lifelong learning comparatively. Before that question can be answered, however, it is necessary to clarify what precisely is lifelong learning and so that constitutes the first part of this chapter. In this section we will argue that a major element of lifelong learning occurs, in its present form, as a result of the process of globalisation and so the second part explores the idea of globalisation and we will endeavour to show that the dominant social forces that are exerted on all aspects of most societies stem from this process, but we will argue in the third section that there are social forces that reinforce these social pressures whilst others seek to mitigate them so that the effects of globalisation do not necessarily result in standardisation. Finally, we will produce a model that allows us to understand how different manifestations of lifelong learning occur and this might form the basis of comparative studies of lifelong learning policies, if not of lifelong learning itself.

Lifelong Learning

Adult educators had long advocated systems of lifelong education (Yeaxlee, 1929) but it only became a dominant issue when the substructures of society needed new knowledge to produce more commodities cheaply and efficiently for the capitalist market. This dominant need has led to the global knowledge economy: countries have been forced to introduce lifelong learning policies and, as a result, there have been massive changes in their education systems. Lifelong learning arrived. Many countries have been forced to change their approach to education which have also been colonised by the global capitalist system – even the most traditional of educational institutions – the universities – have had to change (Bok, 2003; Lucas, 1996; Slaughter & Leslie, 1997).

In analysing lifelong learning, however, we are confronted with a conceptual problem: learning is both an individual process and an institutional provision. Consequently,

we see two different approaches to lifelong learning emerging. Field and Leicester (2000: xvi–xix) pose this issue quite nicely when they ask the question about whether we are dealing with the question of lifelong learning or permanent schooling, although the idea of recurrent might be more accurate than permanent schooling. However, they do not go on to develop the ambiguity that they focus upon in the title of their paper since their chapter is the introduction to their edited book, but other chapters do so. But, it is also a question hidden from the debate by the traditional definition of the concept, such as the one given by the European Commission (2001: 9):

all learning activity undertaken throughout life, with the aim of improving knowledge, skills and competences within a personal, civic, social and/or employment-related perspective.

This is an individualistic definition which is open to question on its instrumental aims, amongst other things. But it is an individualistic interpretation of learning itself and infers the lifelong learner. In this sense, learning is an existential phenomenon which is almost co-terminal with conscious living, i.e. learning is lifelong because it occurs whenever we are conscious and it needs to have no aim in itself, although it frequently does have a purpose. In a sense it is neither incidental to living nor instrumental in itself, it is an intrinsic part of the process of living. It can be defined as:

The combination of processes throughout a life time whereby the whole person – body (genetic, physical and biological) and mind (knowledge, skills, attitudes, values, emotions, beliefs and senses) – experiences social situations, the perceived content of which is then transformed cognitively, emotively or practically (or through any combination) and integrated into the individual person's biography resulting in a continually changing (or more experienced) person. (Jarvis, 2006:134)

This definition has been fully discussed elsewhere (Jarvis, 2006) and so it requires no further elaboration here. However, lifelong learning has a second meaning as indicated above – it is also institutional, a form of recurrent education, which was a popular concept with the Organisation for Economic Co-operation and Development (OECD) and other institutions in the 1970s. But the EU definition also goes beyond this because it allows for the inclusion of initial education, although EC policy documents never really included schooling within its lifelong learning policies. Lifelong learning, therefore, includes formal and non-formal, as well as informal learning. Consequently, we need to recognise this combination of learning and recurrent schooling is another way of understanding lifelong learning and so it may also be defined as:

Every opportunity made available by any social institution for, and every process by which, an individual can acquire knowledge, skills, attitudes, values, emotions, beliefs and senses within global society. (Jarvis, 2007: 99)

Both definitions refer to different approaches to lifelong learning and in a sense they are two sides of the same coin. Learning is always personal but is broader than education

since some of the opportunities to learn throughout our lifetime are provided by social institutions, such as the State and employers in the form of recurrent education. However, one of the major problems with much of the literature on lifelong learning is that it generally refers to work-life learning and it omits all forms of formal and non-formal learning which occur after retirement since they are leisure time pursuits. However, seniors learning is itself a major element in lifelong learning and, significantly, it also began at about the same time that work-life learning was becoming a significant issue.

The first form of institutional provision for seniors began in 1962 in New York, but in 1972 the University of the Third Age was founded in France and by 1982 it was established in the UK but with a different structural form to that on the continent of Europe. By 1988 the Elderhostel Institute Network was formed which included lifelong learning institutes. Consequently, this one non-vocational element of lifelong learning which is large and growing rapidly as the world ages, is open to comparative analyses, and this has grown because of demographics rather than market needs.

In contrast, vocational lifelong learning developed during the same period under a number of different guises such as adult education, continuing education, continuing professional development and human development. It was not until the 1990s that the term lifelong learning came to the fore and this was facilitated by the European White Paper on teaching and learning (European Commission, 1995). The European paper both reflected ideas that were already occurring in some countries in Europe but which were not occurring in less developed countries. Indeed, it was the matter of development that made this change in education so significant, as we will show below, but significantly, work-life lifelong learning did not assume the same terminology in the USA because it had for many years practised a form of adult education which was both vocational and non-vocational, whereas in UK and many other countries adult education was regarded as a leisure time pursuit – which, interesting enough lifelong learning has become in the USA!

However, our concern here is with vocal education for adults, called lifelong learning in Europe but called adult education in the USA, although it is very interesting to note that at about the same time as this chapter was being written a European policy document on adult learning, as opposed to lifelong learning, appeared (European Commission, 2006). Consequently, we now have three different terms: lifelong learning, adult learning and adult education and they each refer to the vocational education of adults. It is the first of these that still has predominance in many countries of the world but it is the phenomenon that, it is argued, has occurred as a result of globalisation and it is to this phenomenon that we now turn.

Globalisation

Many theories of globalisation exist; Sklair (1991: 27–36), for instance, classified the theories of globalisation into five:

- Imperialist and neo-imperialist
- Modernization and neo-evolutionist
- Neo-Marxist (including dependency theories)

- World system (and the new international division of labour theory)
- Modes of production theory

Basically, the imperialist theory argues that the major powers have struggled for new markets and opportunities to extend their political, cultural and economic influence (see Galtung, 1971). The modernisation approach suggests that those underdeveloped societies are constrained by their traditions whereas modern societies are able to reach beyond the tradition; consequently, the modern societies are able to grow and develop since they are led by innovators, usually those whose cultural heritage stems from the Protestant ethic (see Weber, 1930). The most prominent form of neo-Marxist theory is dependency theory. Sklair suggests that there are also theories of dependent underdevelopment, dependent development and dependency reversal, and the work of Bornschier (1980) reflects this position: these theories are closely linked to the imperialist theories. However, other neo-Marxist perspectives would not lay quite so much emphasis on dependency. In Wallenstein's (1974) world system he argued for an international division of labour based upon a centre-periphery model of the world, but like the modernisation theory the significance of power is played down. Finally, the mode of production theories argue that the reasons for underdevelopment lie in the countries themselves rather than the position that the countries are in relation to the global structures. All these recognise the centrality of the economic institution of society although it is only the imperialist and Marxist models that focus on the power in any major way. In themselves all the theories throw some light on globalisation but none explain it fully and only by combining and modifying them can globalisation in contemporary society be explained.

In classical Marxist analysis, the substructure of society was the economic institution – that is, the foundation and framework upon which everything else in society is constructed. In Marx's analysis the economic institution was distinct, but dominant, in each society and so its activities, to some extent, influenced the remainder of society, but they were curtailed by the territorial boundaries of individual states. However, three major things have occurred since that analysis which, while in my opinion does not invalidate the structural approach, actually changes the detail. First, this substructure has now incorporated technology, especially information technology, which has enabled the realignment of space and time, so that, when this is combined with rapid transport systems, the world has been changed into a global village, although the term 'village' is also a little misleading since the world cultures are far less homogeneous than those of a single village, although some theorists are beginning to see it in this manner – a process of standardisation (Beck, 1992) or McDonaldisation (Ritzer, 1993). But secondly, the global village now has this common substructure rather than individual states, so that while the countries still remain separate the substructure is united and its elements can act as single entities across the globe. But this means that the imperialist approach has even more validity. Thirdly, since the fall of the Berlin Wall, there is now only one superpower – the USA – which has exerted itself as the single global imperial power and which has supported the global substructure to such an extent that it is often difficult to distinguish its influence from that of the substructure itself, so that it might be regarded as an element in the substructure at

this moment in time (Pilger, 2003). Since the substructure is supported and defended by the political and military might of the USA, it is predominantly Western so that it is hardly surprising that the idea of Americanisation is often closely associated with that of globalisation. However, this might be only a temporary phase in the development of the world since China and India might soon be the major players. Nevertheless, the capitalist system and the international division of labour do affect a great many of the countries of the world and, therefore, their educational systems. Consequently, the concept of globalisation might best be understood as a socio-economic and political phenomenon having profound cultural implications throughout the globe.

Globalisation has at least two main elements: the first is the way that those who have control of the substructure in the countries of the dominant West, especially America, have been enabled to extend their control over the substructures of almost all the other countries in the world and consequently over their structures and resources; the second is the effects that these substructural changes are having on the superstructure of each society since the common substructure means that similar forces are being exerted on each people and society despite each having different histories, cultures, languages, and so on, but these forces do not exist unopposed since different cultural groups seek to retain their own ways of life. In addition, individual States and national governments are still powerful and they also seek to oppose or modify the forces of globalisation. I have called this mitigation while Habermas (2006: 81) refers to it as cushioning, but the fact that governmental policies can mitigate the effects of globalisation gives rise to both convergence and difference, and this is as true for lifelong learning policies and practices as it is for other social phenomena.

Globalisation can thus be depicted by Figures 1 and 2.

The significance of this model is that there is a global substructure represented here by the core running through all the different countries – it exercises a centralised power over each of the countries and, in this sense, it is a force for convergence between the different countries of the world. The large downward pointing arrows illustrate that there is a relationship of power between the 203 countries of the world (this is the number recorded by UNESCO, 2006), while the two small black upward pointing arrows depict the resistance to the forces of globalisation. In the above diagram each stratum represents a country which is penetrated through the centre by the substructure, and each country can now be represented in the following manner.

The concept of a multilayered society was first utilised by Held *et al.* (1999: 62–77) and the layers are depicted hierarchically in order to illustrate that it is not merely a geographical matter but that it is also one of power stemming from the core to the periphery, although it has to be recognised that power is not a one-way process since, by the nature of democracy the ‘lower orders’ can and should be proactive as well, but there is for a variety of reasons a degree of passivity amongst individuals to the pressures coming from the hierarchy since many enjoy comfortable lifestyles. Neither individuals nor organisations are depicted here but they can exercise influence and power in any one of the layers of society.

The first thing to note about Figures 1 and 2 is that the substructure is united and runs through all the different countries, and so the two layers in Figure 1 depict only two

Figure 1. A global model of societies

Figure 2. A multilayered model of society

of the many countries that we could have included and they have to negotiate between themselves in order to cooperate. The development of information technology, rapid travel, and so on means that people throughout the world are much more aware of what occurs elsewhere and are much more able to affect it. It is possible, therefore, for people at different levels in the hierarchy to communicate across national boundaries electronically, to travel rapidly and cheaply between different countries, so that there is intercultural sharing, but they are still separate politically and culturally. The external arrows represent the unequal relationships between each country; for instance, the dominant downwardly pointing arrow represents trade, aid, consultations, and so on. There is certainly more giving by the more powerful to the less powerful countries, so that the arrows still depict a hegemonic relationship in which the dominant cultures of the West still export their culture and commodities but through a different mechanism.

By contrast, the united substructure runs through each country making similar demands on each, as Beck (2000) suggests, it criss-crosses national boundaries since its constituent members agree on the aims and functions of the centre, but there is also internal competition within the core since each constituent company is competing with many others in order to produce commodities that can be marketed throughout the world more successfully than their rivals. The fact that there is internal competition means that the speed of change within the core is fast, driven by the demands of the market, which it is both a creating force and one to which all strands of the core are seeking to respond. It is, therefore, changing faster than those aspects of the global system that are not so market-driven and so it produces a force for change in each country. Additionally, it is necessary to recognise that change is neither gradual nor even, since new discoveries tend to generate change unevenly. The significance of this fact is that for new commodities to be produced and marketed, both new knowledge and an educated workforce are necessary and so the educational system has to change to keep abreast with these changes, including the fact that in some ways education has to be skewed towards the workforce and so vocational education has to become lifelong. The last thing that is necessary to note here is that there are in both diagrams arrows indicating that there are forces opposing the dominant globalising forces and that these influence different states and their policies differently, so that standardisation is not the outcome of globalisation although there are strong pressures towards it. There are many other effects of globalisation and these have been elaborated elsewhere (Jarvis, 2007) but discussion about them is unnecessary to the argument of this chapter.

The substructure (or core), then, is the driving force of each society, but within the national and local cultures there are both wider interests and concerns than those to be found in the core and also in some instances a degree of resistance to the changes that are occurring and these are to be found at every level, including the international. It is the substructure of global society that not only drives change but also creates change in the educational system. Education has been incorporated into the wider political and economic system, and as early as 1973, Kerr *et al.* (1973: 47) noted that education was the handmaiden to industry and that:

The higher educational of industrial society stresses the natural sciences, engineering, medicine, managerial training – whether private or public – and

administrative law. It must steadily adapt to new disciplines and new fields of specialization. There is a relatively smaller place for the humanities and the arts, while the social sciences are strongly related to the training of managerial groups and technicians for the enterprise and the government. The increased leisure time of industrialism, however, can afford a broader public appreciation of the humanities and the arts.

Of course, they were wrong about the nature of society but they were right about the emphasis being placed on scientific and useful subjects, albeit in the post-industrial society. Stehr (1994: 10–11) suggests that there has been an advance of science in the knowledge economy. Naturally, the dominant educational discourse in the knowledge societies is about the precedence of practical, scientific and relevant social science knowledge. Other forms of knowledge can be relegated to leisure time pursuits and so lifelong learning became equated with work-life learning in Europe but with leisure time pursuits in the USA! But in the latter work-life learning is included within adult education. It must be made clear here that the European concept of lifelong learning is used hereafter, and especially the distinction that I have drawn between lifelong learning and lifelong (or recurrent) education.

However the forces of change have not gone unchallenged and lifelong learning does not appear in every country in the same form: it is this that is important for comparative education.

Towards a Model for Comparative Lifelong Learning

From the argument presented above, we are in a position to see that the dominant forces are the ones which have shaped lifelong education in most countries of the world – but that there are other forces at international, national and even regional and local levels that either reinforce, seek to modify or even oppose these dominant forces and Figure 3 below depicts the argument thus far.

If the above model has validity, it should provide a theoretical framework for understanding the different pressures being exerted on the state and other providers of education generated by the forces of globalisation. It should therefore be indicative of the form that lifelong learning takes in different societies of the world. It should be noted, however, that since the core has no power of state that it can only generate pressures while the international can both generate pressures and formulate policies; the national and regional can generate pressures, formulate policies and initiate practices. In this way it is possible for all the layers to cushion the population from the harshest pressures of global capitalism or to reinforce them. There are, therefore, five brief subsections to this part: global and international pressures, national and regional policies and resisters to change.

Global Pressures

Emanating from the centre, the global pressures are the forces for change. For instance, the aims of global capitalism are to produce new commodities as cheaply and efficiently as possible and to sell them at the maximum profit on the market. In order to produce

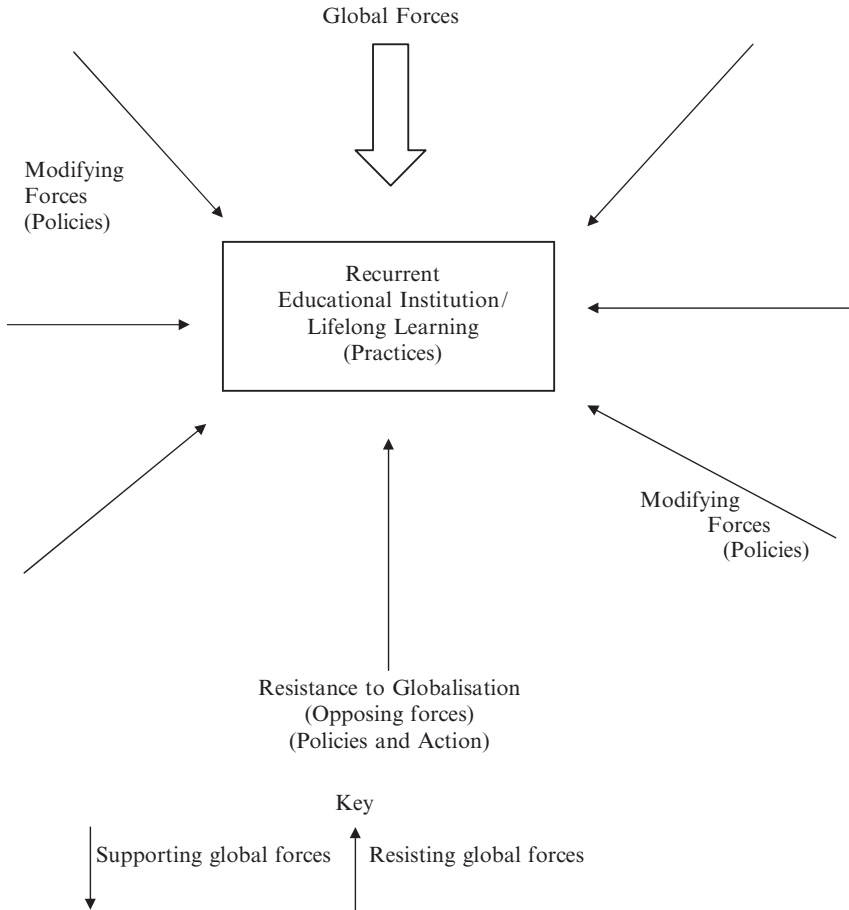

Figure 3. The educational institution in social context in a globalising world

new commodities or even to produce old ones more efficiently, it is necessary to have new knowledge which is practically orientated and an employable workforce, i.e. an educated one. Consequently, some forms of knowledge take precedence over others: Scheler (1980), as early as 1926, argued that some forms of knowledge – scientific and technological – are artificial since they change so quickly that they never become incorporated in culture whereas cultural knowledge changes very slowly. These forms of knowledge change as rapidly as the market demands and so workers and potential employees need first an initial education that makes them employable and then continuing occupational development so that they can remain employable. If they do not have it, then they are excluded from the workplace, so that the global forces demand certain emphases in the curriculum and lifelong learning and if they do not get it, then the corporations either relocate their production to cheaper and more malleable places and/or they start their own corporate universities (Meister, 2000; Jarvis, 2001). These forces operate in each country of the world but to varying degrees.

International

The international agencies also exert pressures throughout the world in a variable manner: all three forms – support, modification and resistance are noted here. There is also an almost complete spectrum of approaches to lifelong learning at this level – we will briefly refer to four – World Bank, UNESCO, OECD, and the European Union.

Within the framework, therefore, the World Bank, and the International Monetary Fund, as neo-liberal economic institutions, exert social pressures on governments that reinforce the pressures of the substructure and therefore serve to reproduce the social and cultural conditions of global society (see Pilger, 2003). This pressure is even greater on those countries to which the World Bank has loaned or supported the loan of money, since it can place conditions on the developing countries to conform to its own understanding of global economics, even if such economics do not appear beneficial to the countries concerned: they are certainly beneficial to the developed world, and the large corporations, which invest in them the corporations' profit. Indeed, Joseph Stiglitz (2002) the World Bank's former chief economist and Nobel Laureate in Economics has recently claimed that the time has come for major changes in the World Bank's economic policy and the values – he (2002: 252) writes that 'development is not about helping a few rich people get rich . . . it is about transforming societies, improving the lives of the poor, enabling everyone to have a chance at success and access to health care and education' (cited from Bawden, 2006: 113). He makes the same criticism of the International Monetary Fund. At the same time, it has to be acknowledged that in many instances loans are a way of kick-starting an initiative for some of those who are autonomous, strong-willed and entrepreneurial.

In contrast, we find in UNESCO a completely different picture: a champion of lifelong education having adopted the term long before it gained popularity, it has both led the way in developing the concept but, at the same time, always presenting it within a humanistic perspective. From its first major report, Faure Report (UNESCO, 1972) and the publication of the background papers (OISE-UNESCO, 1973) to the present day we see the same concerns. Produced before global capitalism became such a dominant force, the Faure Report is the outcome of a UNESCO Commission on the Development of Education, and yet its conclusions are still relevant today. In order to give a flavour of this report, we find a different emphasis since the whole of the person is constantly emphasised:

The physical, intellectual, emotional and ethical integration of the individual into the complete man is a broad definition of the fundamental aim of education. (italics in original; Faure, 1972: 156)

In Faure's Preamble (pp. xix–xxxiv) the nature of the human being is clearly specified:

- Uniting *Homo sapiens* and *Homo faber* is not enough – such a man must also feel in harmony with himself and with others: *Homo concors*.
- This is the age total *man*: that is to say, man entire and all of man.

This was a far-sighted and radical Report which has left its mark on the world of education but the extent to which its concerns have been taken on board is another matter. But UNESCO has been consistent as some of its later publications demonstrate (UNESCO, 1990; 2000; 2005, *inter alia*)

Unlike the World Bank, these UNESCO documents are liberal utopian, full of the significance of humankind, and how humankind as a whole needs to enjoy the fruits of the world in which we live. It is liberal utopian, ethical but also political seeking to modify and redirect the forces of social change emanating from the substructure of global society. But there are many other important organisations offering their own solutions to these problems and we need to examine some of these. We will now examine the OECD.
